

promhx

Programming Reactive Object Methods in Haxe

A bit about me...

Data Visualization + Data
Science + Machine Learning +
Advanced UI

I “Promhx” to explain...

```
var p = new Promise<Explanation>();
```

```
var s = new Stream<Examples>();
```

```
var d = new Deferred<Understanding>();
```

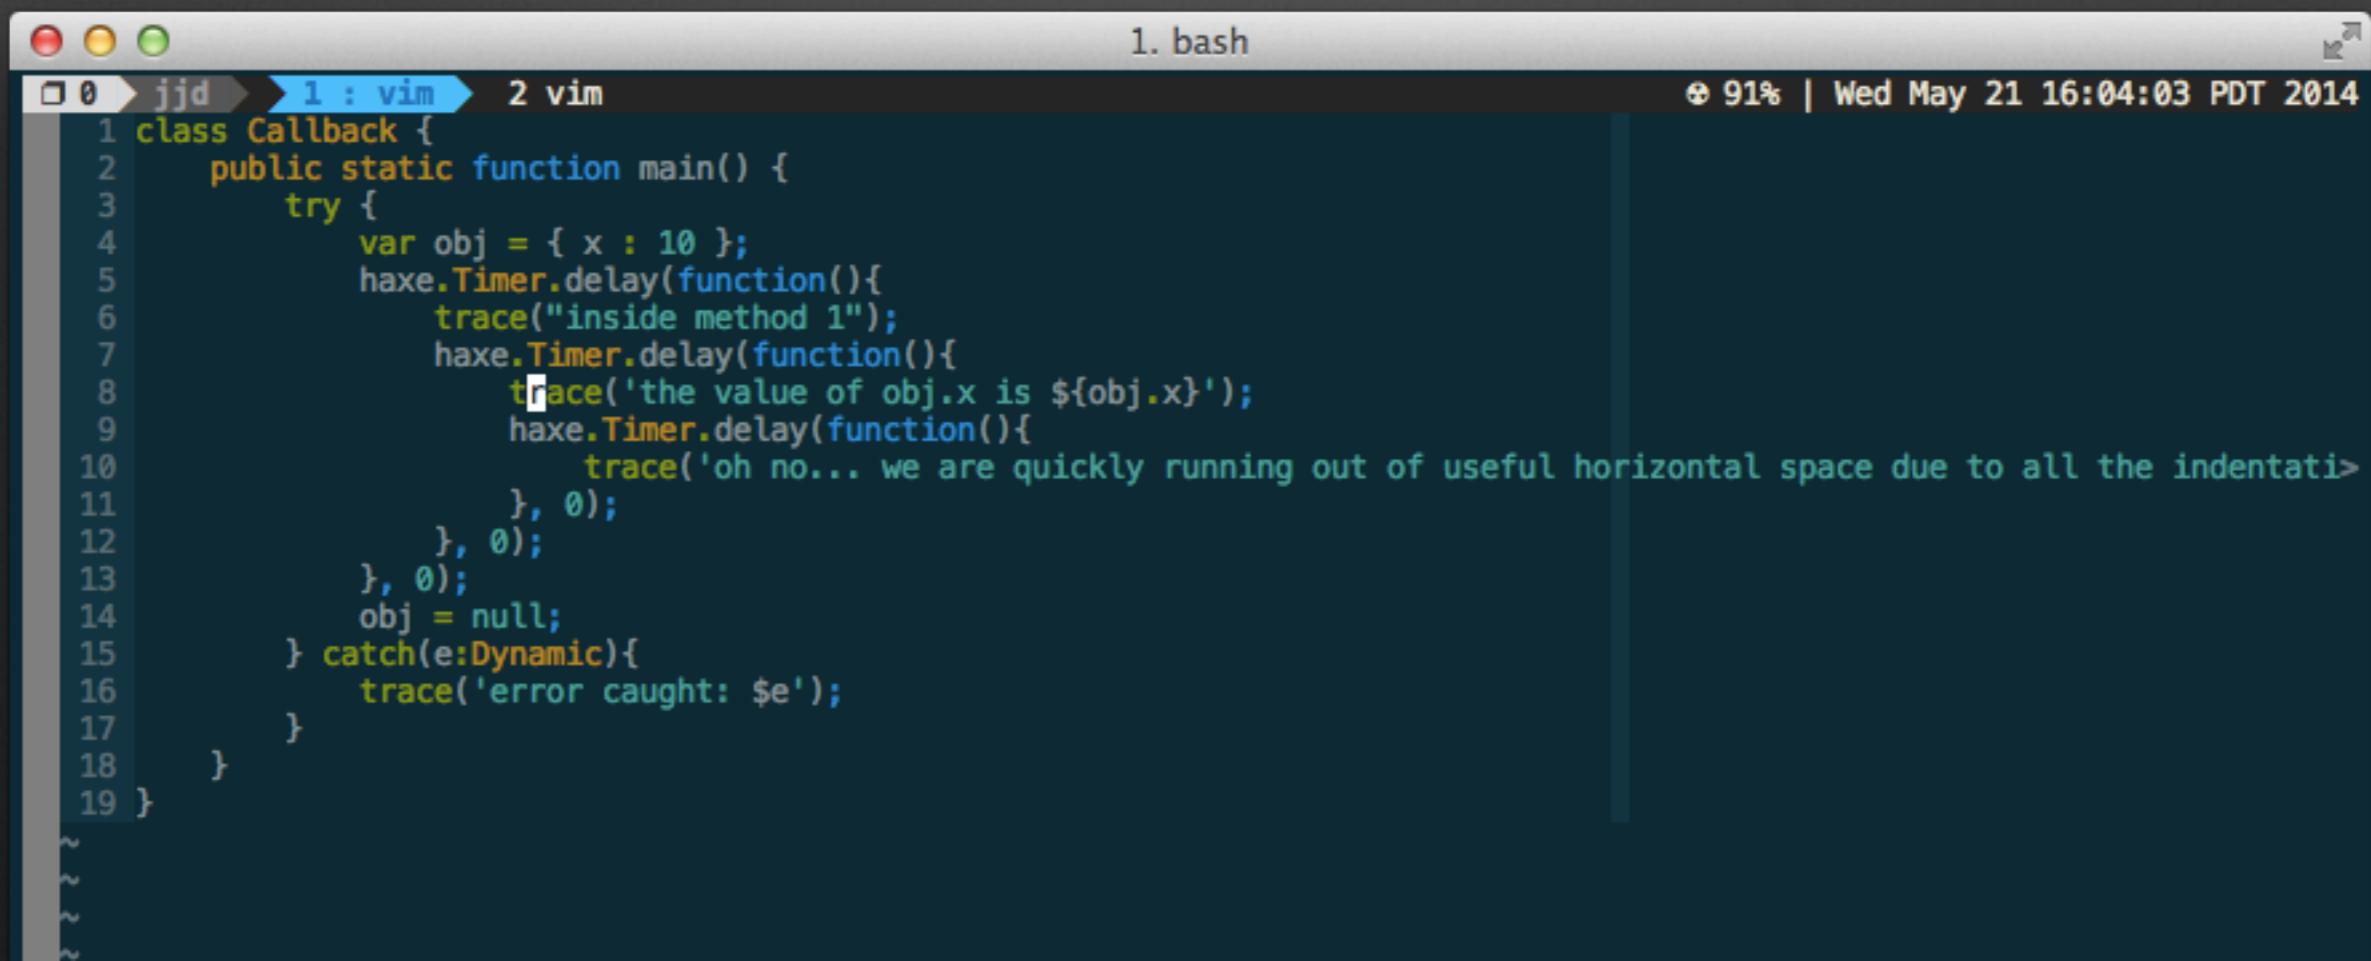

But first some background...

Asynchronous Programming

- *Client code is often single threaded. Excessive time delays due to computation causes rendering lag, and can block IO.*
We often need to **break up computation** in multiple loops.
- *Client code often handles server responses through asynchronous callbacks.*
We need to **wait for the server** to respond.
- Managing error handling often involves **careful use of try-catch** in several locations. It is difficult to ensure all exceptions are caught.
We want a **better way of handling generic errors**.
- *Callbacks generally follow a nested pattern*
Nested code indentation patterns can become **difficult to read**.
- *Server side platforms are finding success with asynchronous programming techniques, with the same opportunities and pitfalls (nodejs). However, server side implementations often have different methods of managing asynchronous callbacks.*
We want to **implement asynchronous code the same way on client/server**.

Asynchronous Programming

How many potential problems in this code?

A screenshot of a Mac OS X terminal window titled "1. bash". The window shows a command history at the top: "jjd" (highlighted in blue), "1 : vim" (highlighted in blue), and "2 vim". The main pane displays a Haxe script named "1.bash". The script contains the following code:

```
1 class Callback {
2     public static function main() {
3         try {
4             var obj = { x : 10 };
5             haxe.Timer.delay(function(){
6                 trace("inside method 1");
7                 haxe.Timer.delay(function(){
8                     trace('the value of obj.x is ${obj.x}');
9                     haxe.Timer.delay(function(){
10                         trace('oh no... we are quickly running out of useful horizontal space due to all the indentations');
11                         }, 0);
12                         }, 0);
13                         }, 0);
14                         obj = null;
15                     } catch(e:Dynamic){
16                         trace('error caught: $e');
17                     }
18                 }
19 }
```

The terminal status bar at the bottom right indicates "91% | Wed May 21 16:04:03 PDT 2014".

Asynchronous Programming

Lost space due to indentation

```
1. bash
 0 jjd > 1 : vim > 2 vim
1 class Callback {
2     public static function main() {
3         try {
4             var obj = { x : 10 };
5             haxe.Timer.delay(function(){
6                 try {
7                     trace("inside callback 1");
8                     haxe.Timer.delay(function(){
9                         trace("inside callback 2");
10                    trace('the value of obj.x is ' + obj);
11                    haxe.Timer.delay(function(){
12                        trace('oh no... we are quickly running out of user horizontal space due to all the indentation');
13                    }, 0);
14                }, 0);
15            } catch (e: Dynamic){
16                trace('error caught: ' + e);
17            }
18        }, 0);
19        obj = null;
20    } catch(e:Dynamic){
21        trace('error caught: ' + e);
22    }
23 }
```

Missed error handling

Not *really* 0 seconds

Duplicate error handling

Functional Reactive Programming to the Rescue

Wikipedia : “*In computing, reactive programming is a programming paradigm oriented around **data flows and the propagation of change**. This means that it should be possible to express static or dynamic data flows with ease in the programming languages used, and that the underlying execution model will **automatically propagate changes through the data flow**.*”

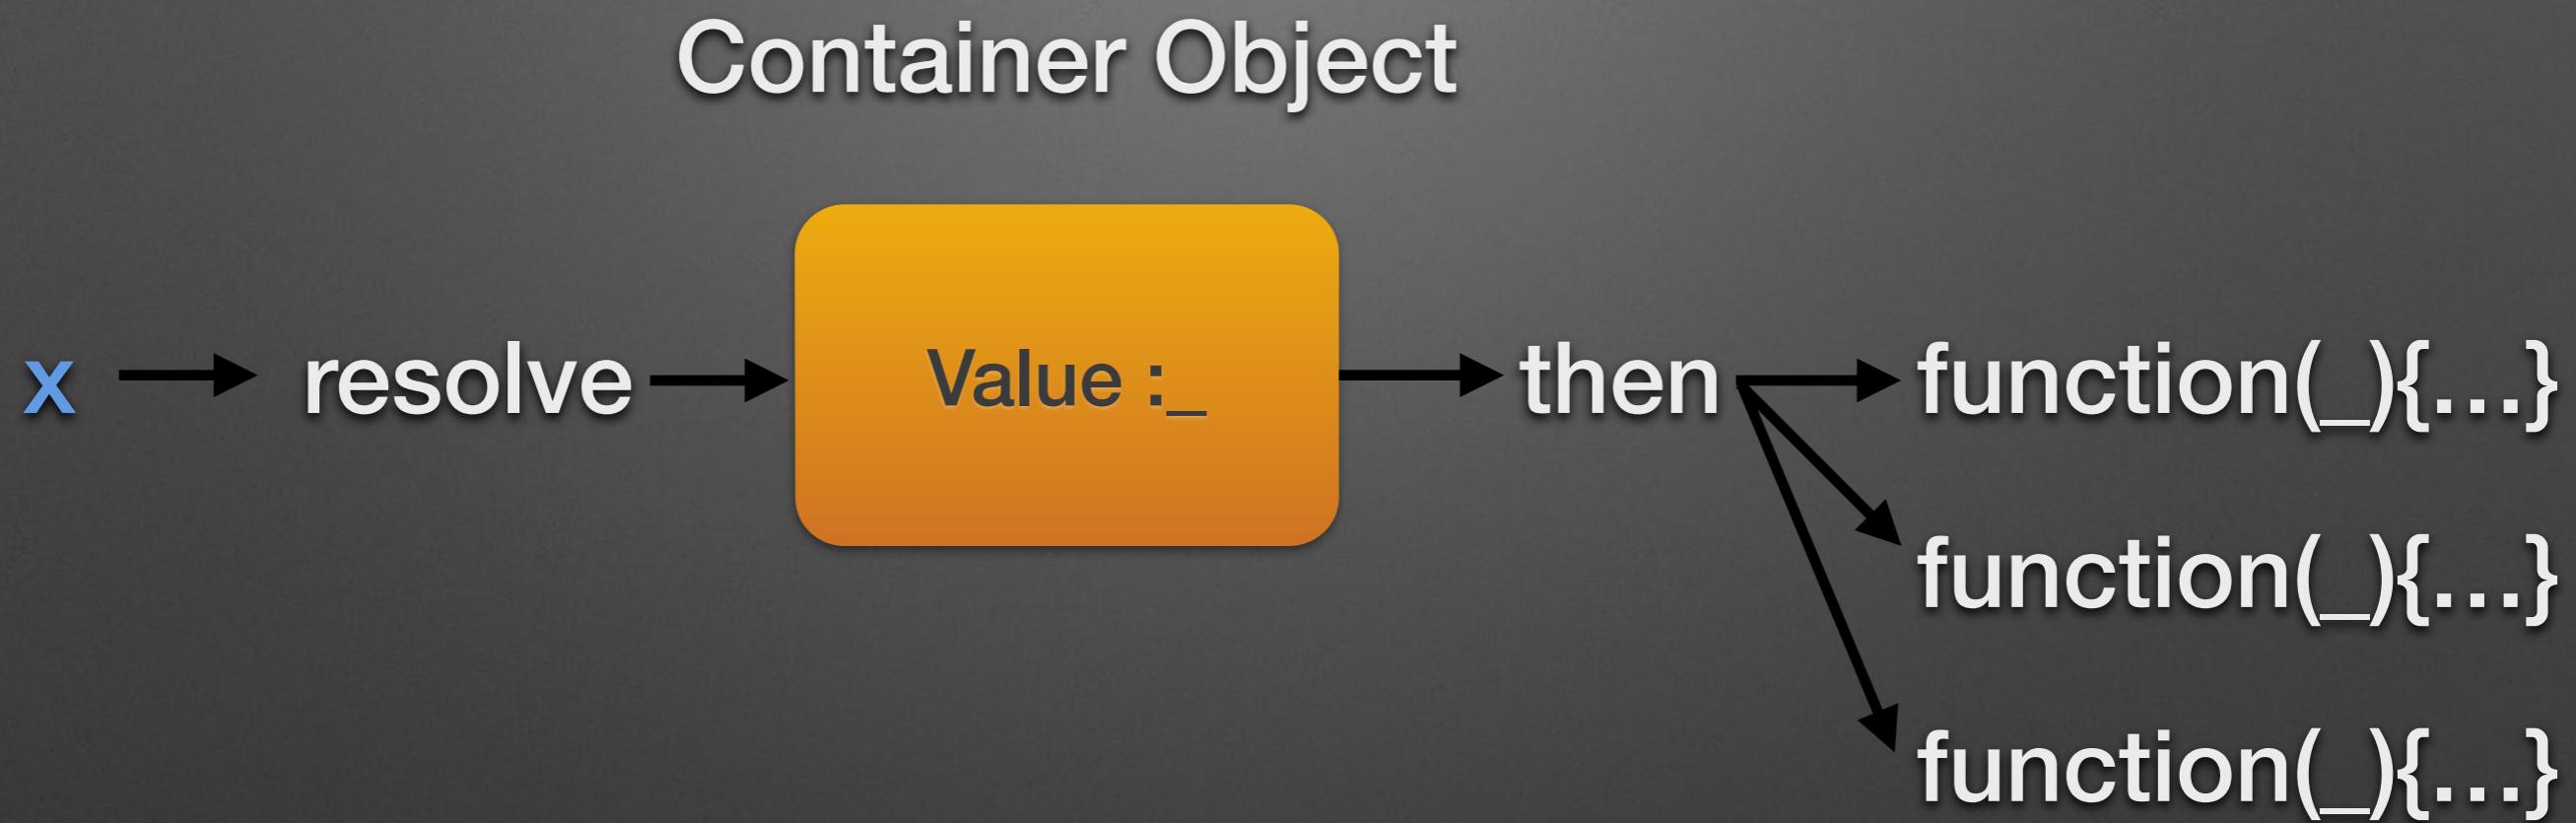

Reactive programming moves the unit of asynchronous programming from a **callback** to a **special object**. It is a **variable over time**.

What is a Promise?

Wikipedia : “*In computer science, future, promise, and delay refer to constructs used for synchronizing in some concurrent programming languages. They describe an object that acts as a proxy for a result that is initially unknown, usually because the computation of its value is yet incomplete.*”

What is a (Reactive) Stream?

Wikipedia : “In computer science, a stream is a sequence of data elements made available over time. A stream can be thought of as a conveyor belt that allows items to be processed one at a time rather than in large batches.”

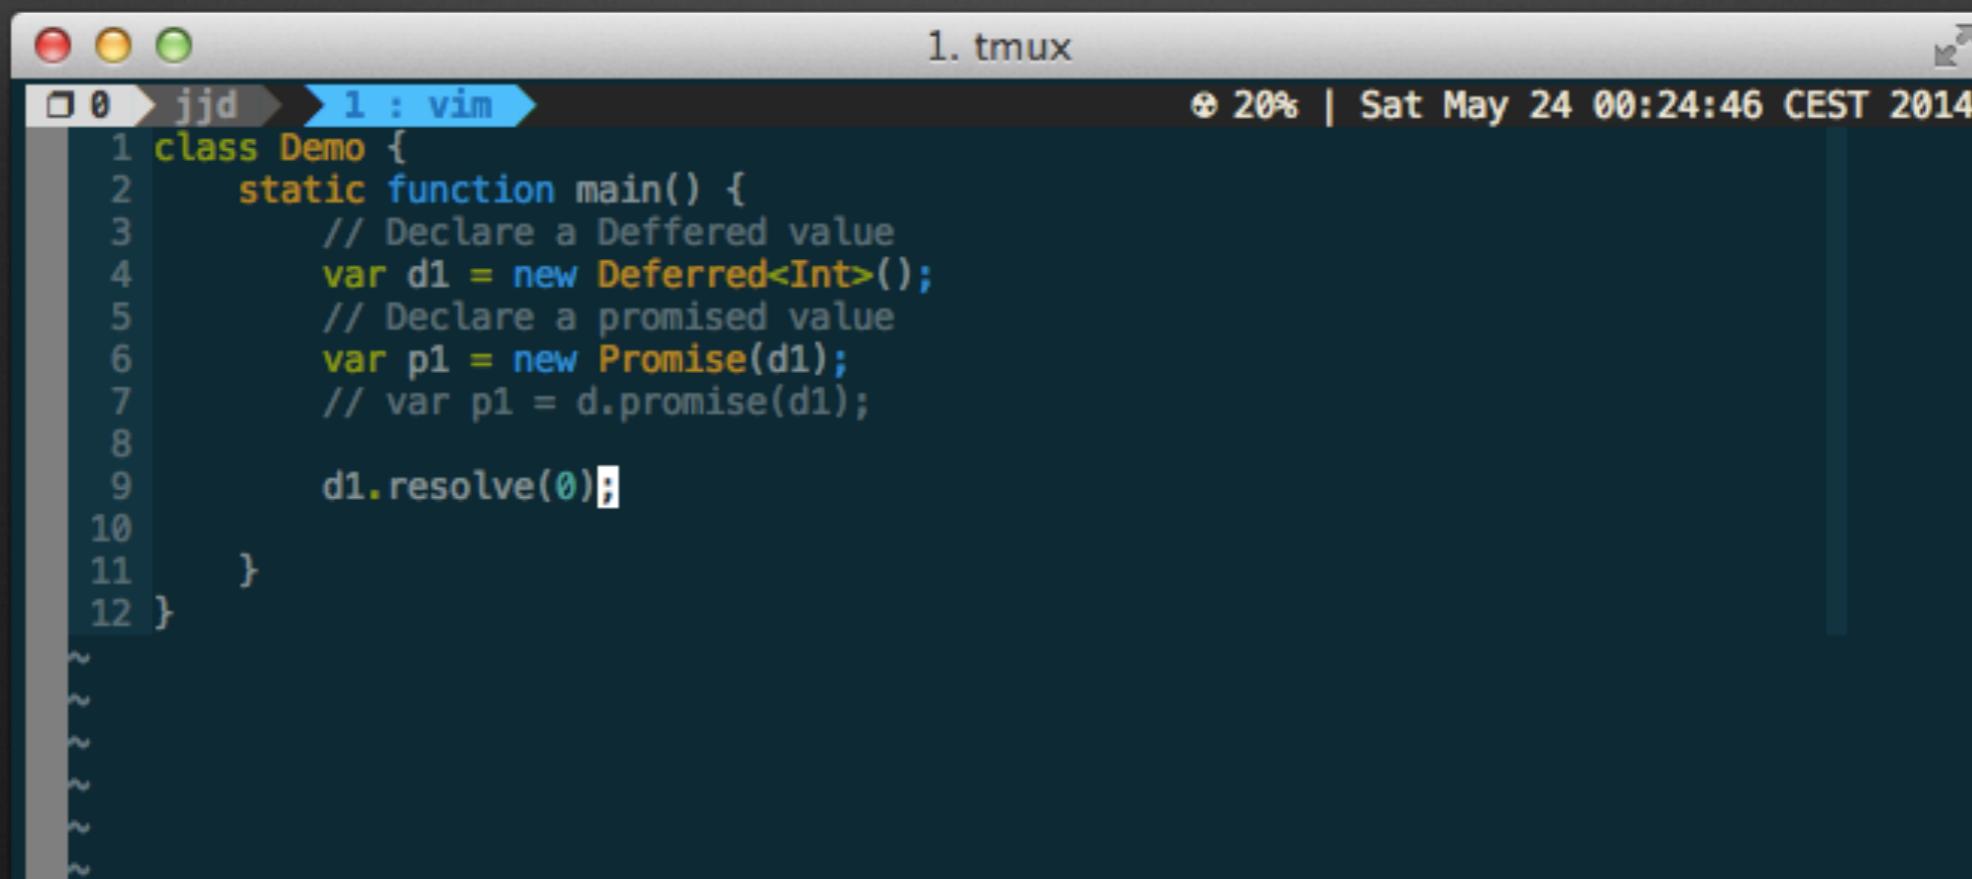

Promises vs. Streams

- Promises
 - Good for providing initial configuration, and ensuring that an asynchronous workflow progresses “forward”.
 - Can only **resolve once!**
- Streams
 - Good for providing general-purpose reactive programming.
 - **Resolves more than once.**
- Promises **and** Streams
 - Generally, promises can be substituted where streams are expected, but not vice-versa.
 - Both provide the same error semantics, and optimized asynchronous event loop management.
 - Both use **Deferreds** as a writable interface...

What is a Deferred?

Deferreds are a **writable interface** for reactive objects. Use them to prevent other developers from mistakenly resolving a Promise or Stream that they should not have access to.*

*The notable exception is PublicStream, which is globally write-accessible.

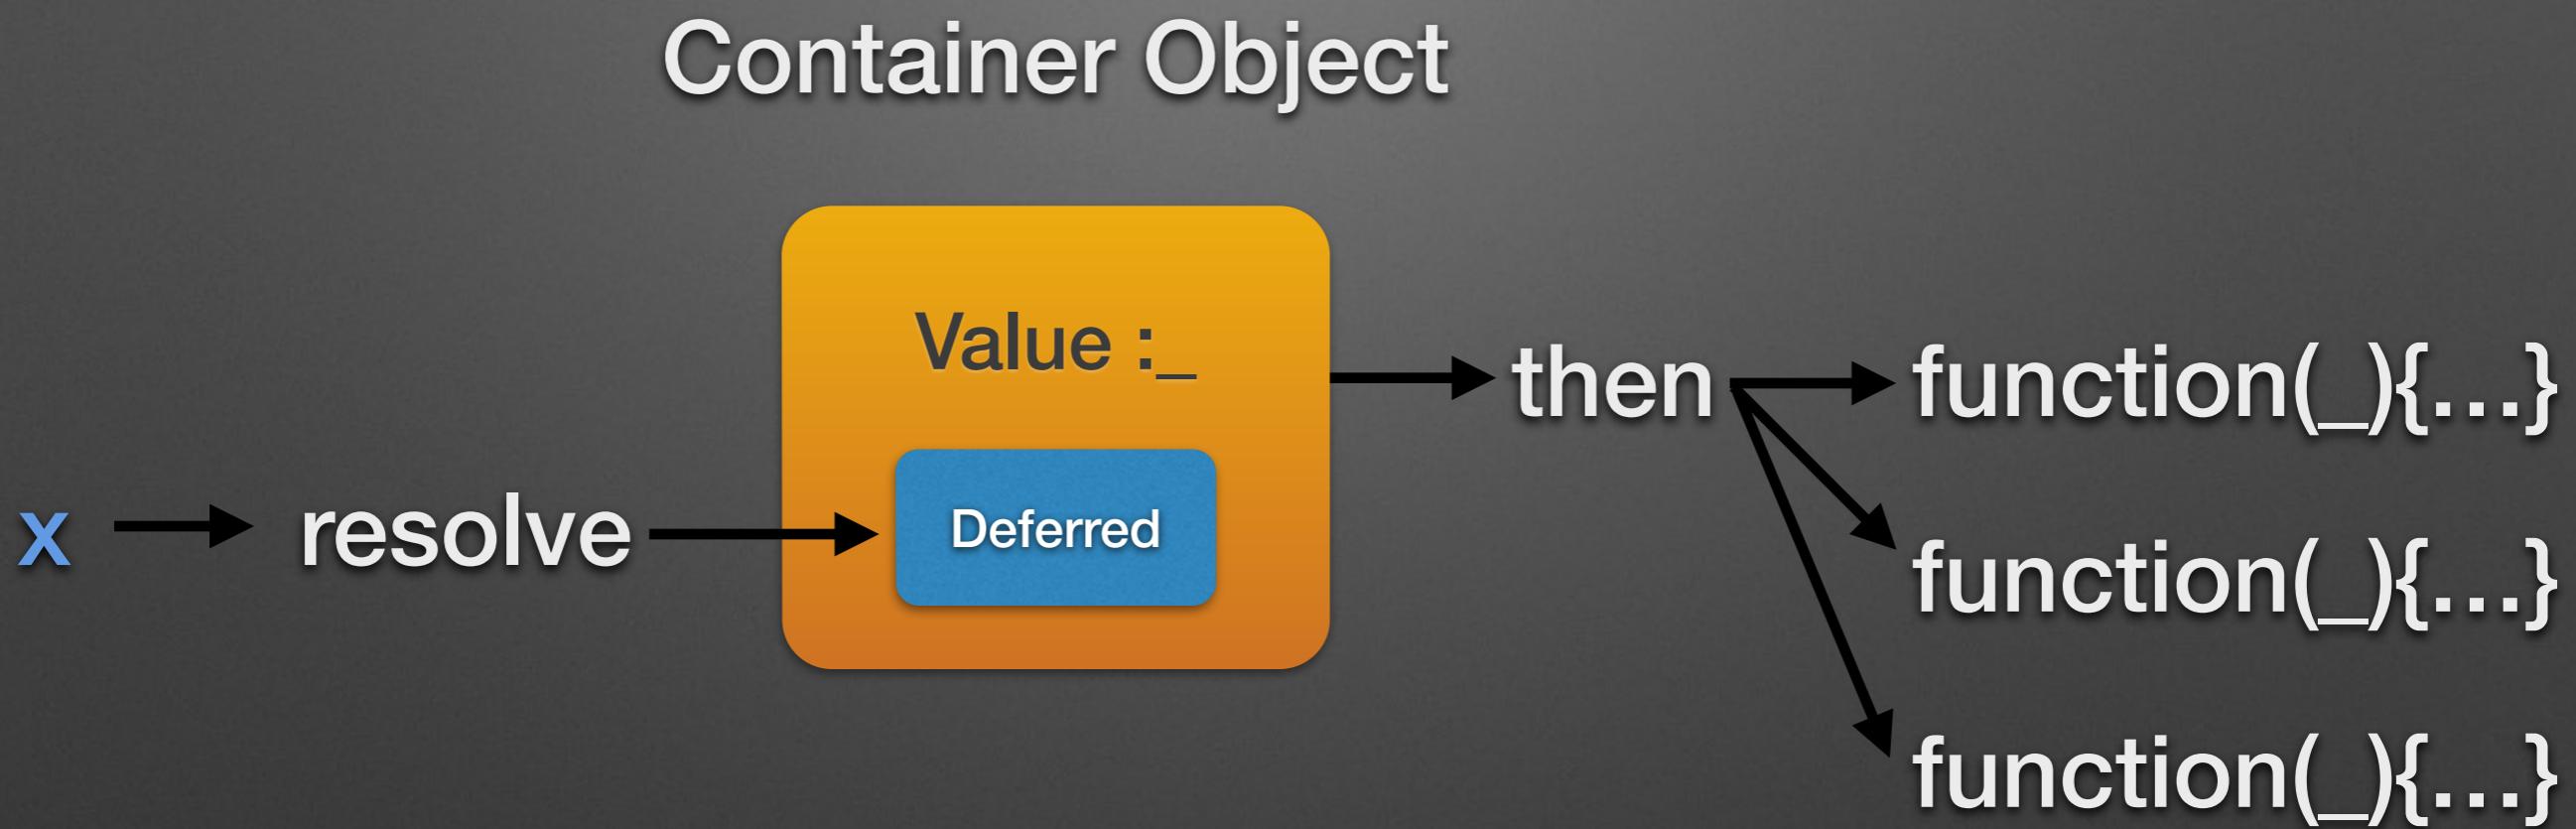

The screenshot shows a tmux session titled "1. tmux" with one window active. Inside the window, a vim editor is open displaying the following Java code:

```
1 class Demo {  
2     static function main() {  
3         // Declare a Deffered value  
4         var d1 = new Deferred<Int>();  
5         // Declare a promised value  
6         var p1 = new Promise(d1);  
7         // var p1 = d.promise(d1);  
8  
9         d1.resolve(0);  
10    }  
11 }  
12 }
```

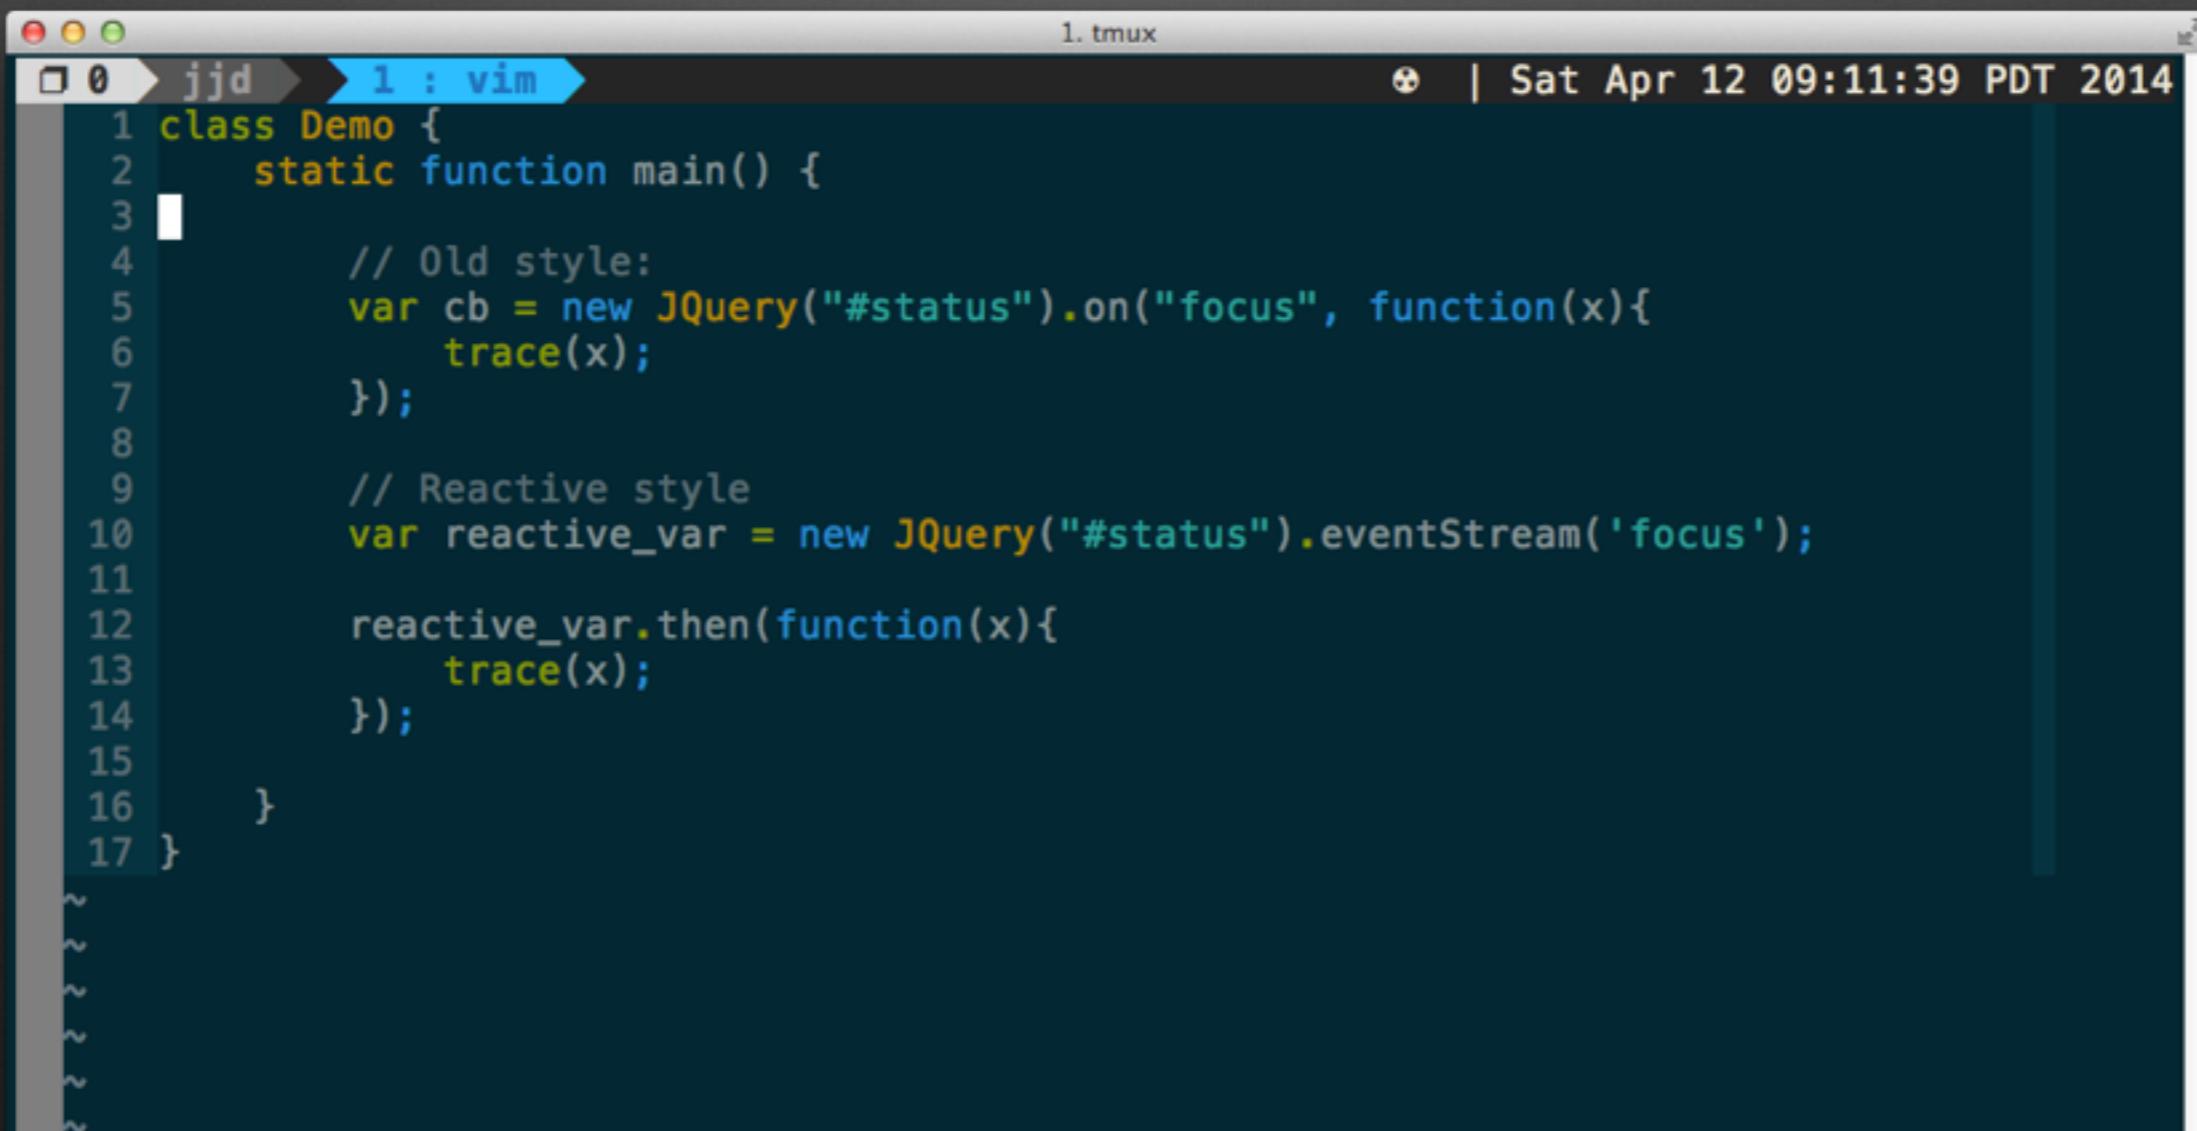

The code demonstrates the creation of a Deferred object and its resolution. The tmux session also shows the status bar with "20%" battery level, the date "Sat May 24 00:24:46 CEST 2014", and the tmux session ID "1. tmux".

What is a Deferred?

Basics of Reactive Programming in Promhx

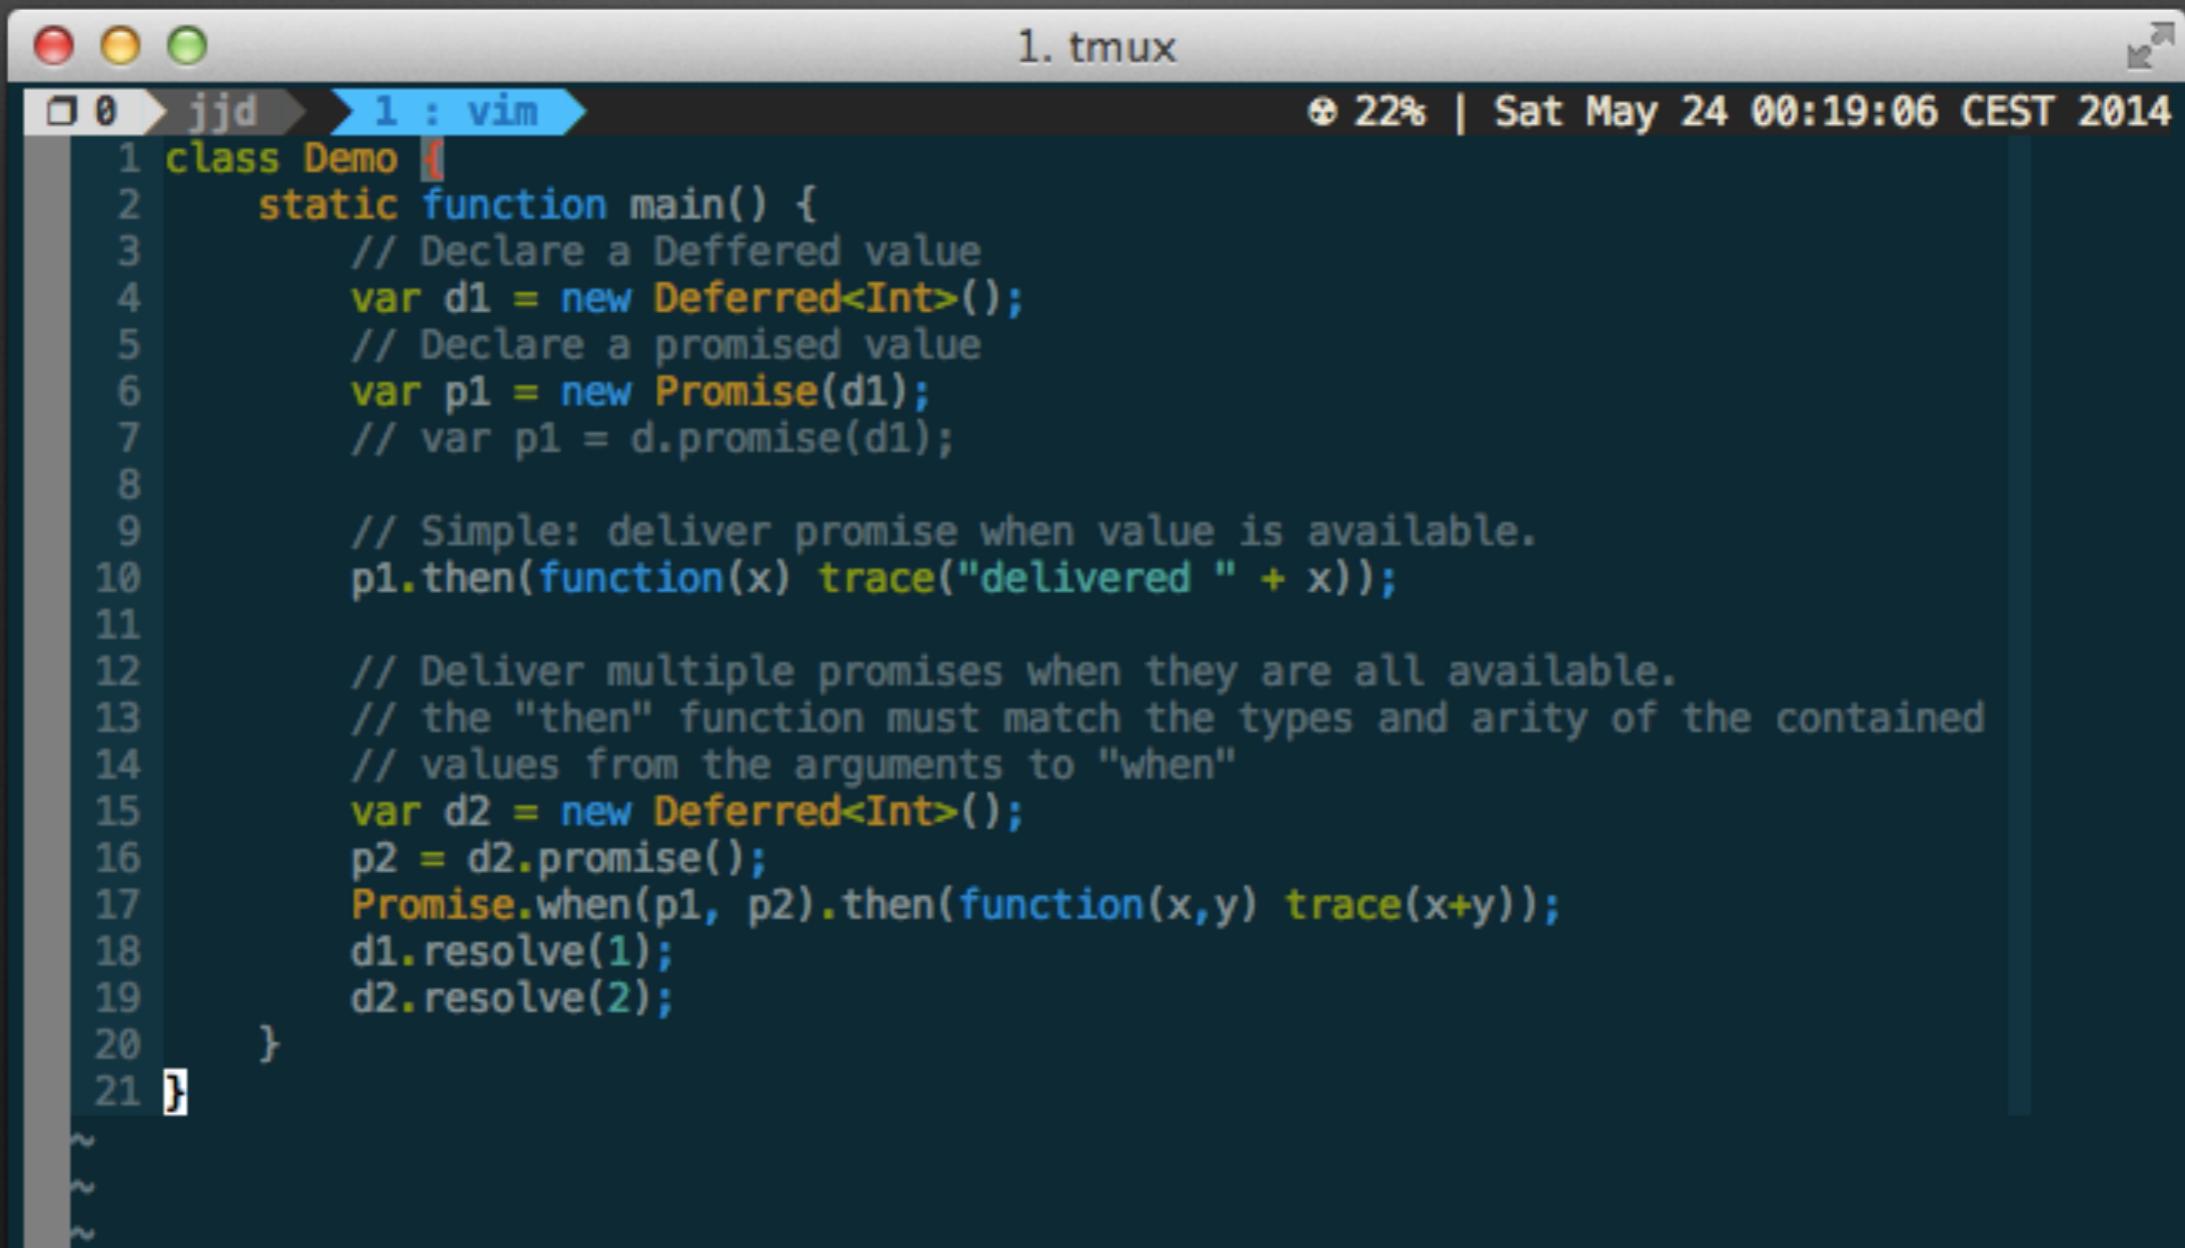

Move the callback to the proxy object

A screenshot of a tmux session titled "1. tmux". The window contains vim code for a file named "1 : vim". The code compares two styles of reactive programming using jQuery. The first style is "Old style" where a callback function is passed directly to the .on() method. The second style is "Reactive style" where a callback function is passed to the .then() method of a Stream object returned by .eventStream().

```
1 class Demo {
2     static function main() {
3
4         // Old style:
5         var cb = new JQuery("#status").on("focus", function(x){
6             trace(x);
7         });
8
9         // Reactive style
10        var reactive_var = new JQuery("#status").eventStream('focus');
11
12        reactive_var.then(function(x){
13            trace(x);
14        });
15
16    }
17 }
```

Basics of working with Promises

then vs. when : instance vs. static usage

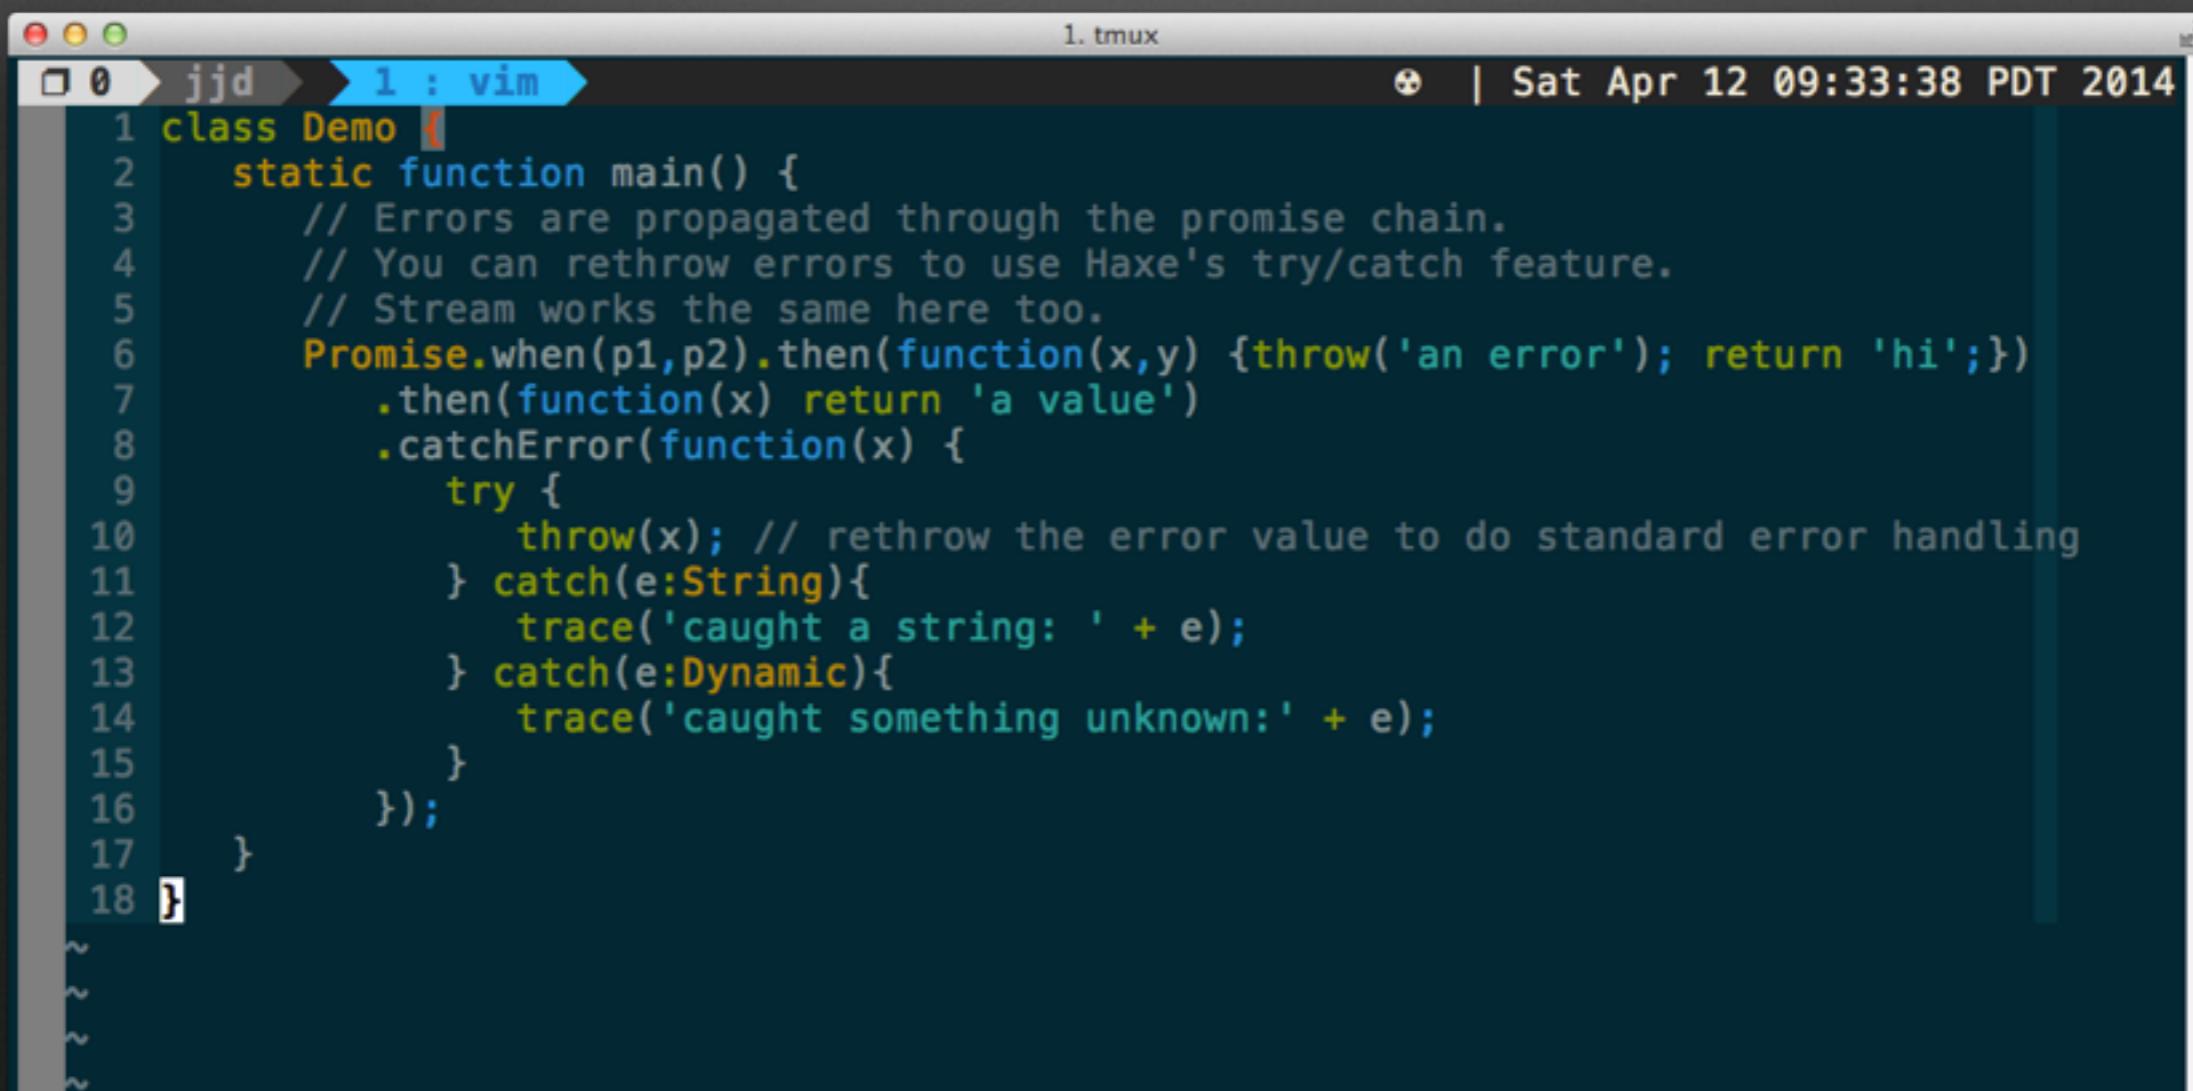

The screenshot shows a tmux session with one window titled "1 : vim". The code in the buffer illustrates the difference between `then` and `when` methods for promises.

```
1. tmux
  0:jjd>1:vim
  22% | Sat May 24 00:19:06 CEST 2014

1 class Demo {
2     static function main() {
3         // Declare a Deffered value
4         var d1 = new Deferred<Int>();
5         // Declare a promised value
6         var p1 = new Promise(d1);
7         // var p1 = d.promise(d1);
8
9         // Simple: deliver promise when value is available.
10        p1.then(function(x) trace("delivered " + x));
11
12        // Deliver multiple promises when they are all available.
13        // the "then" function must match the types and arity of the contained
14        // values from the arguments to "when"
15        var d2 = new Deferred<Int>();
16        p2 = d2.promise();
17        Promise.when(p1, p2).then(function(x,y) trace(x+y));
18        d1.resolve(1);
19        d2.resolve(2);
20    }
21 }
```

Error handling

- Errors are propagated through the reactive chain
- `catchError()` functions like a try/catch, preventing updates to other reactive variables.
- Use Haxe's try/catch semantics to catch typed errors.

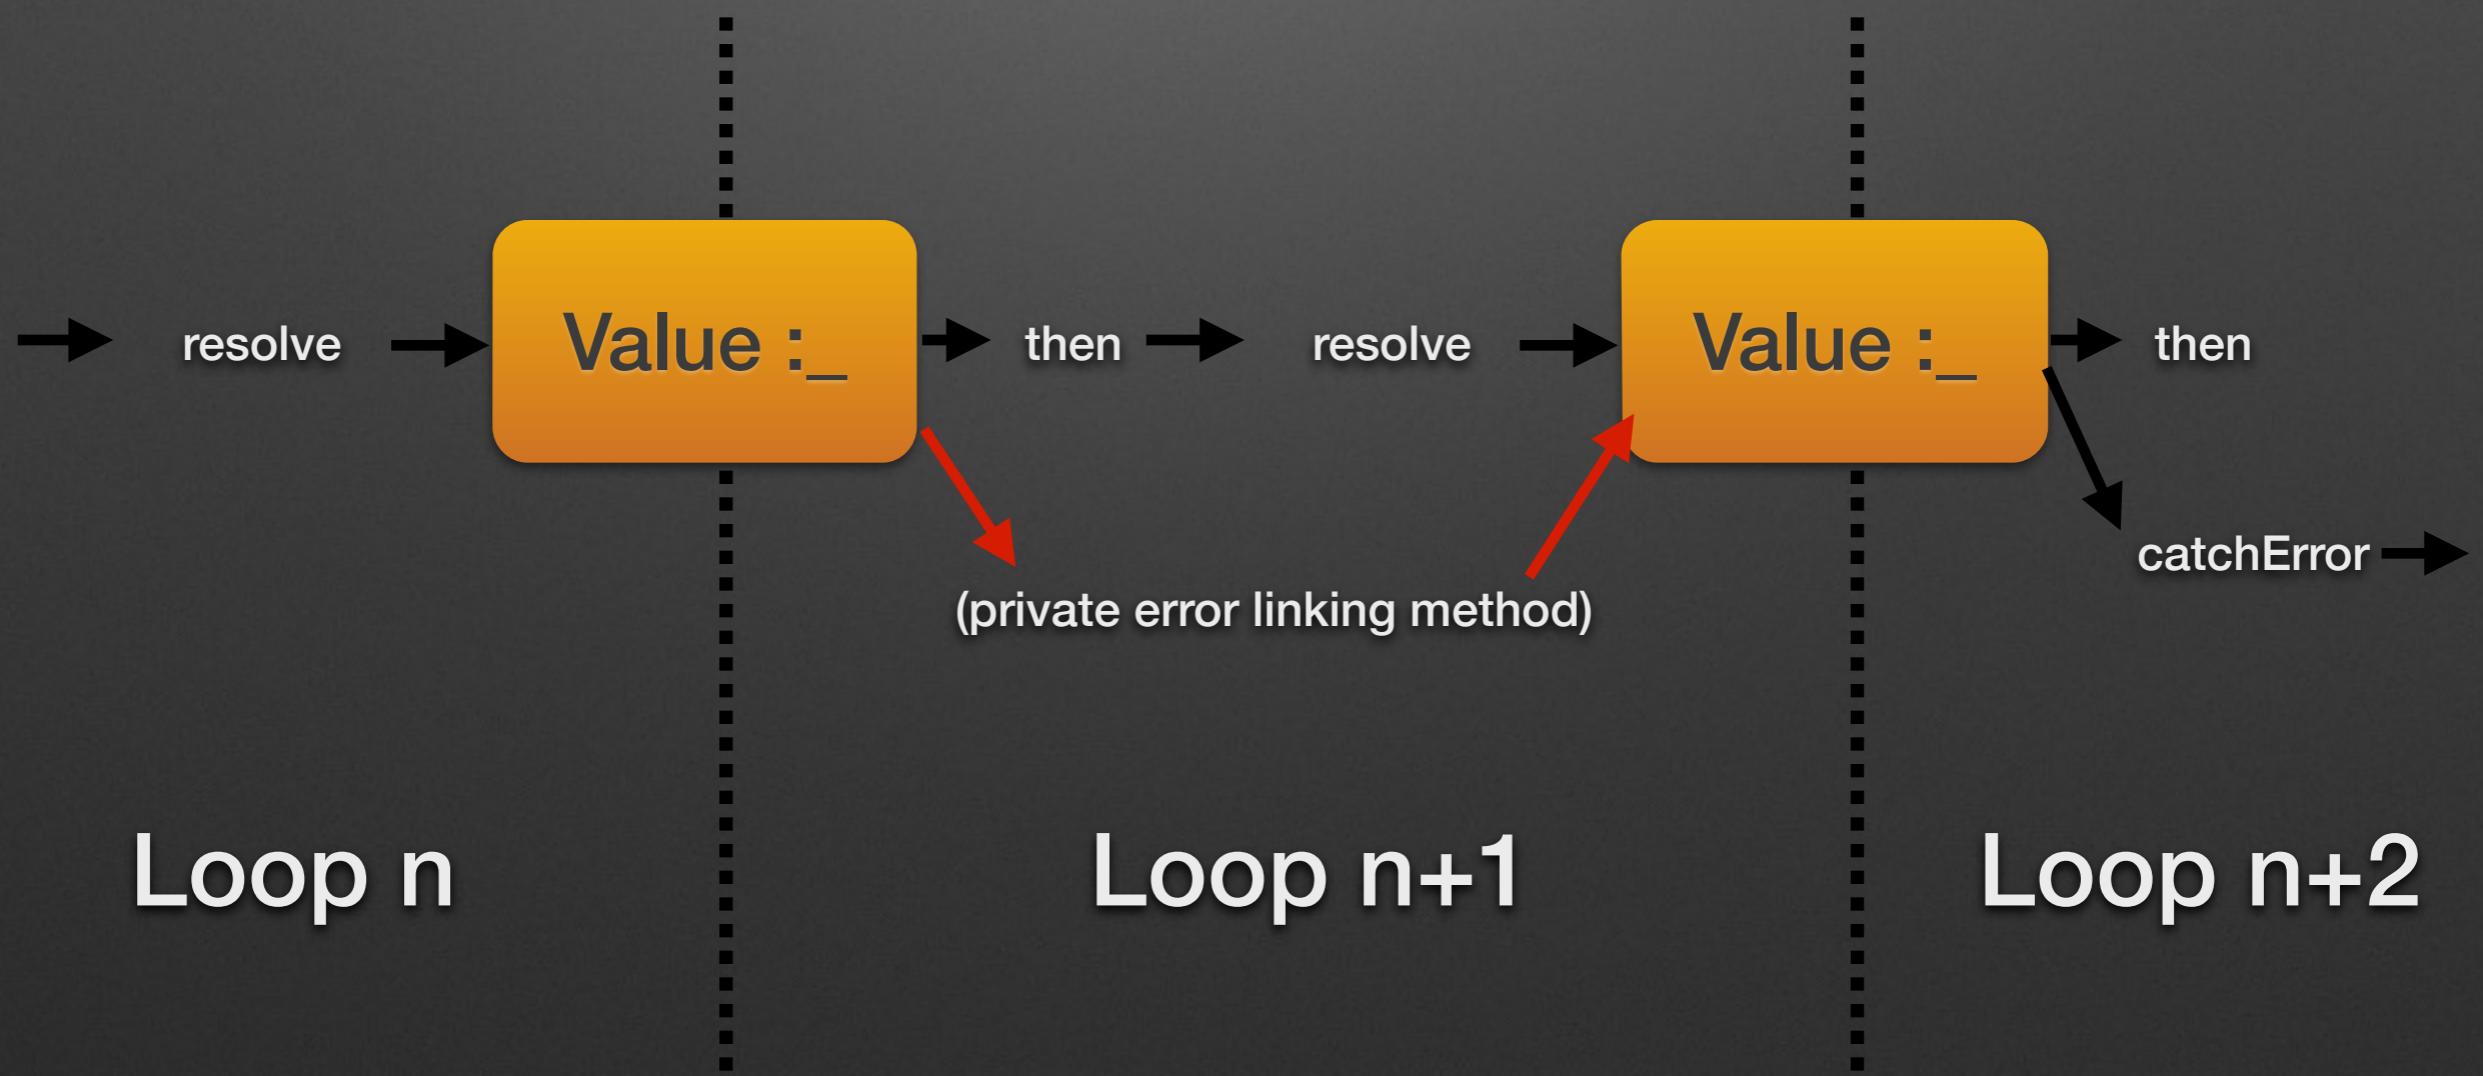

A screenshot of a tmux session titled "1. tmux". Inside, a vim window shows the following Haxe code:

```
1 class Demo {
2     static function main() {
3         // Errors are propagated through the promise chain.
4         // You can rethrow errors to use Haxe's try/catch feature.
5         // Stream works the same here too.
6         Promise.when(p1,p2).then(function(x,y) {throw('an error'); return 'hi';})
7             .then(function(x) return 'a value')
8             .catchError(function(x) {
9                 try {
10                     throw(x); // rethrow the error value to do standard error handling
11                 } catch(e:String){
12                     trace('caught a string: ' + e);
13                 } catch(e:Dynamic){
14                     trace('caught something unknown:' + e);
15                 }
16             });
17     }
18 }
```

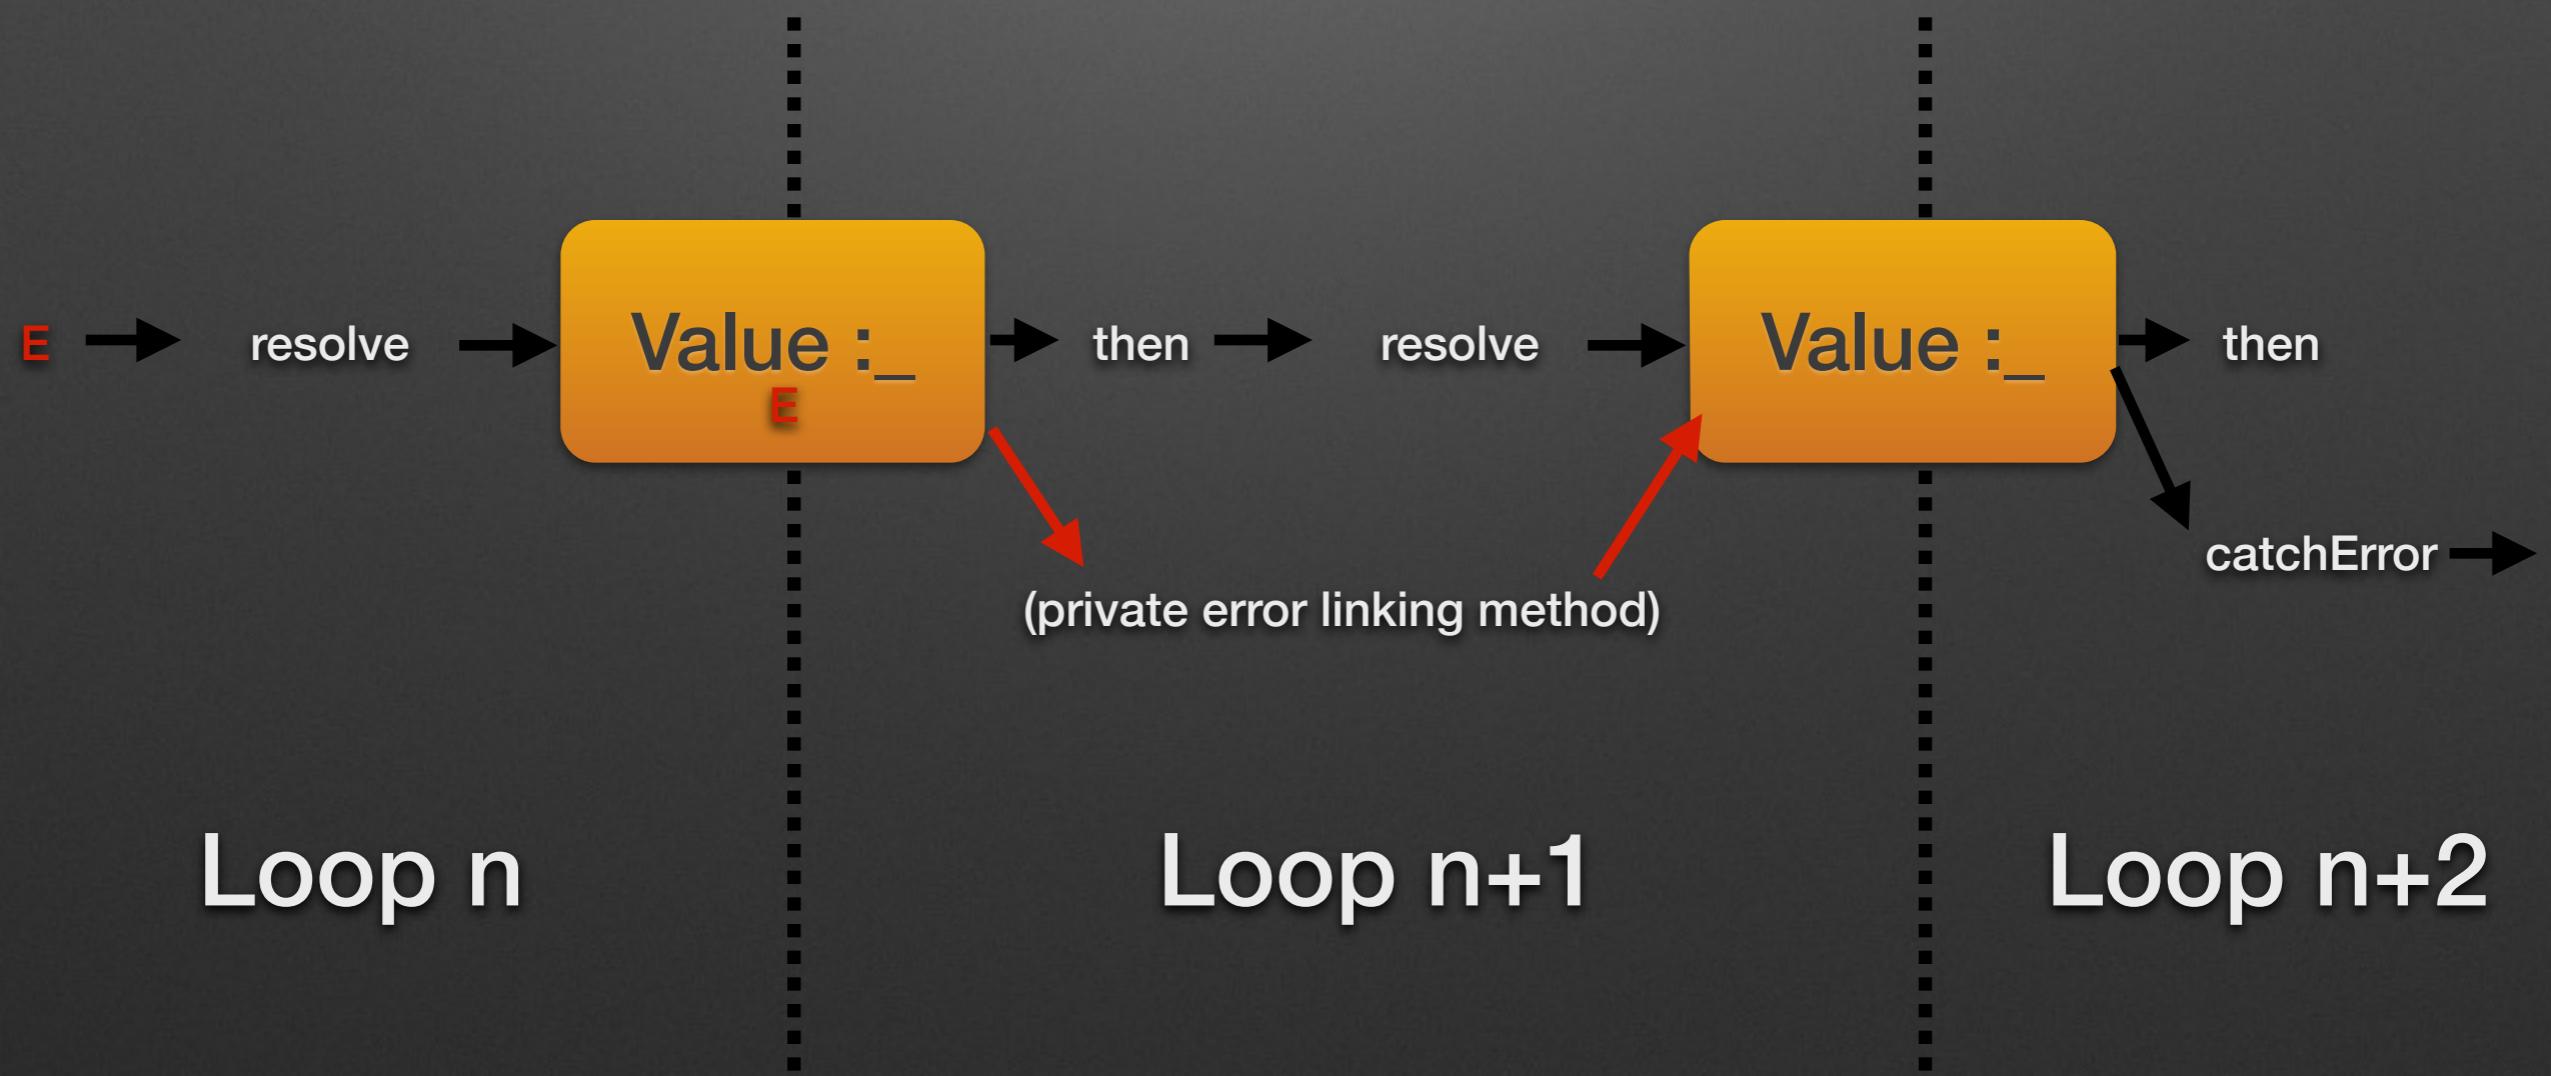

Promhx Object

Error Handling

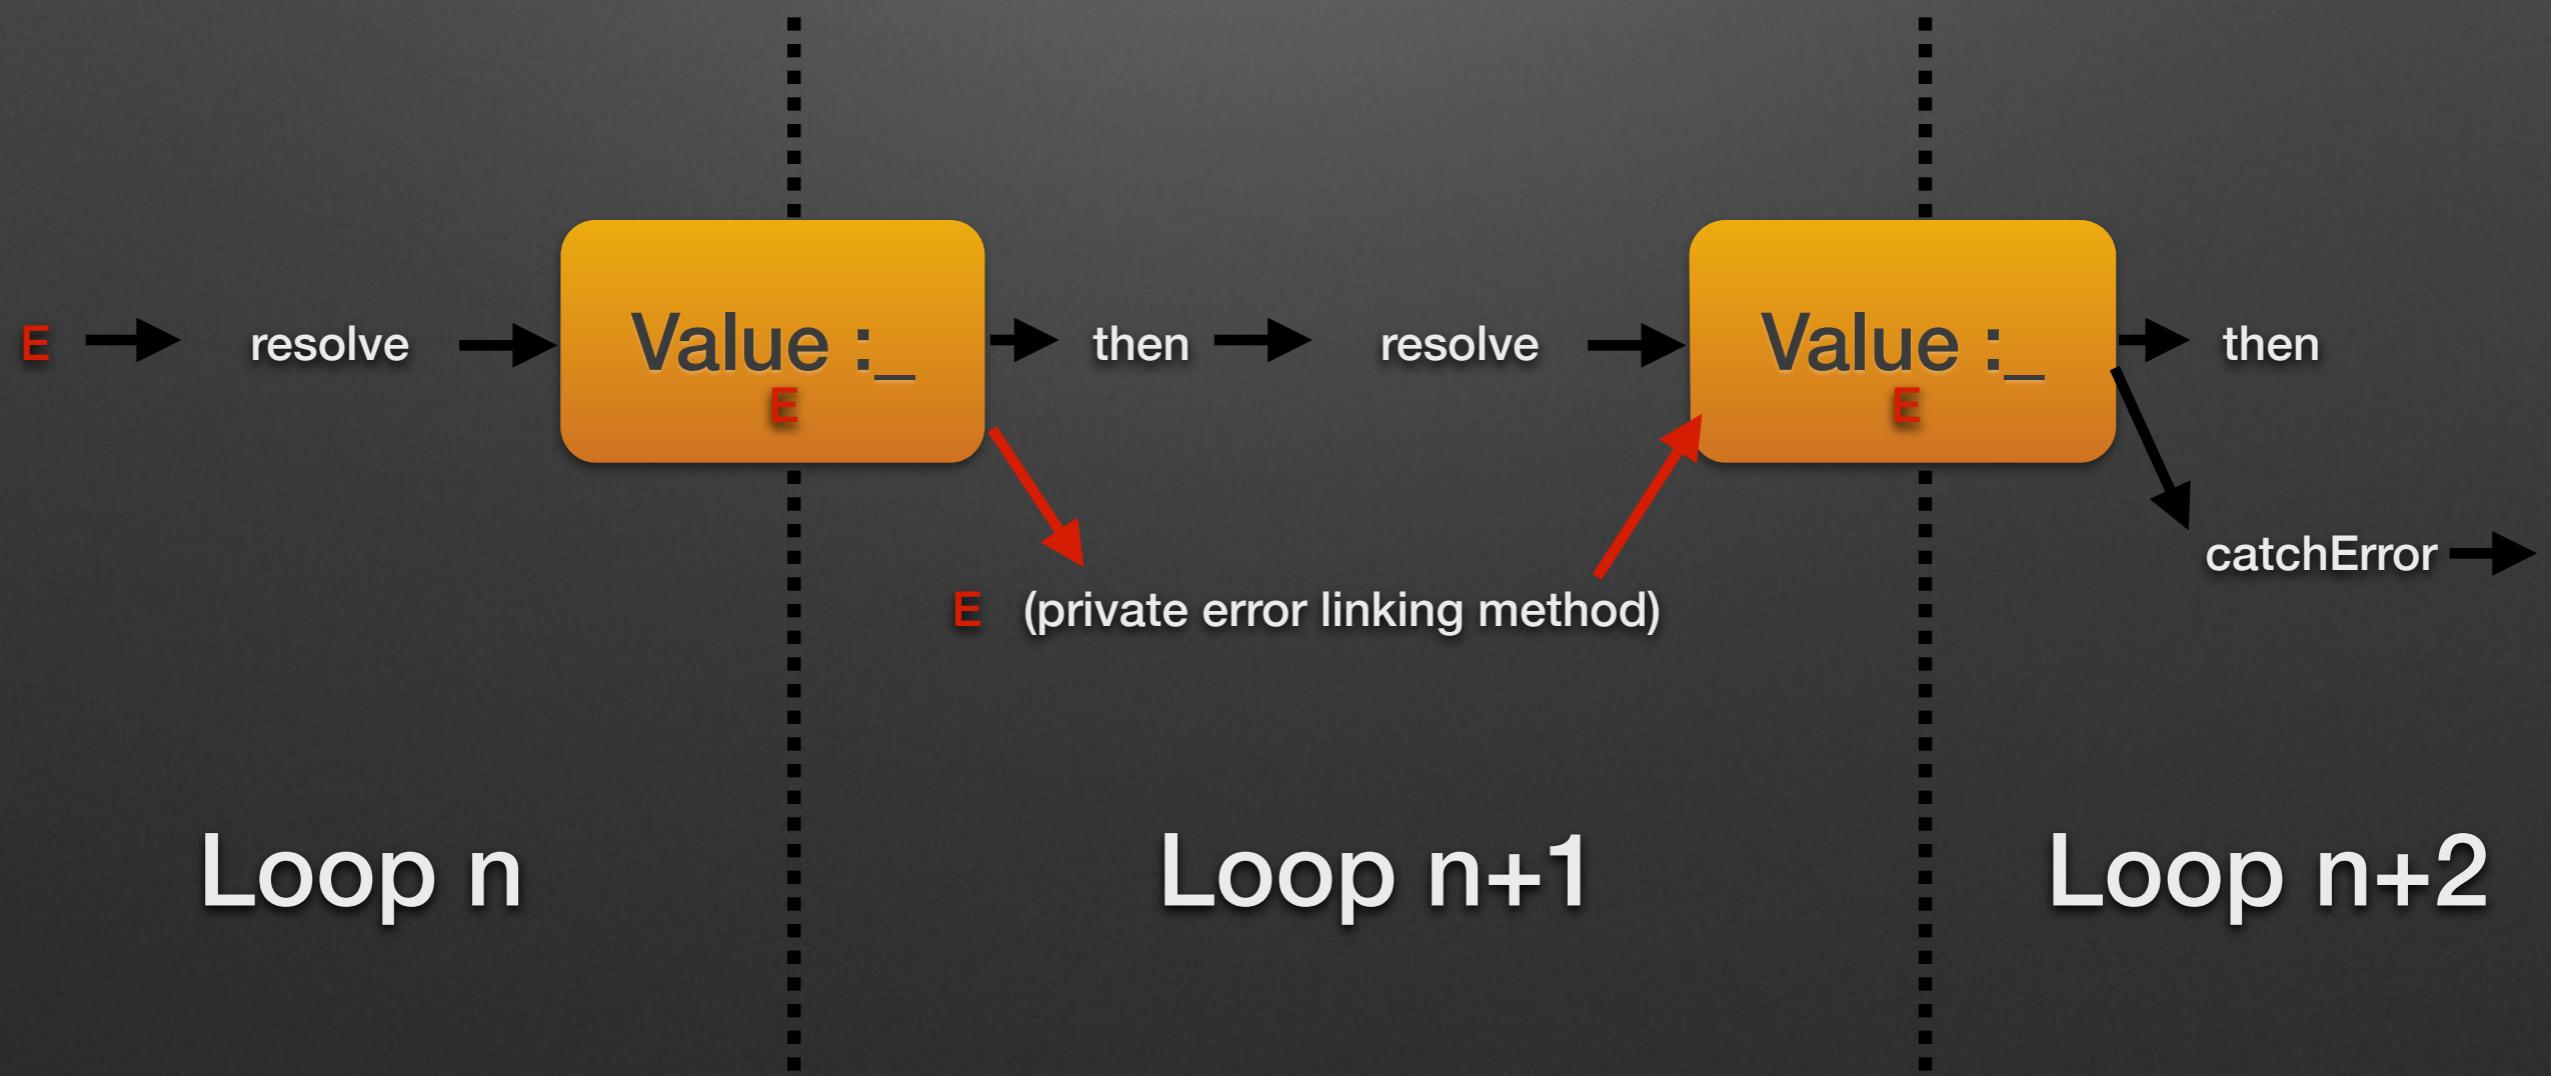

Promhx Object

Error Handling

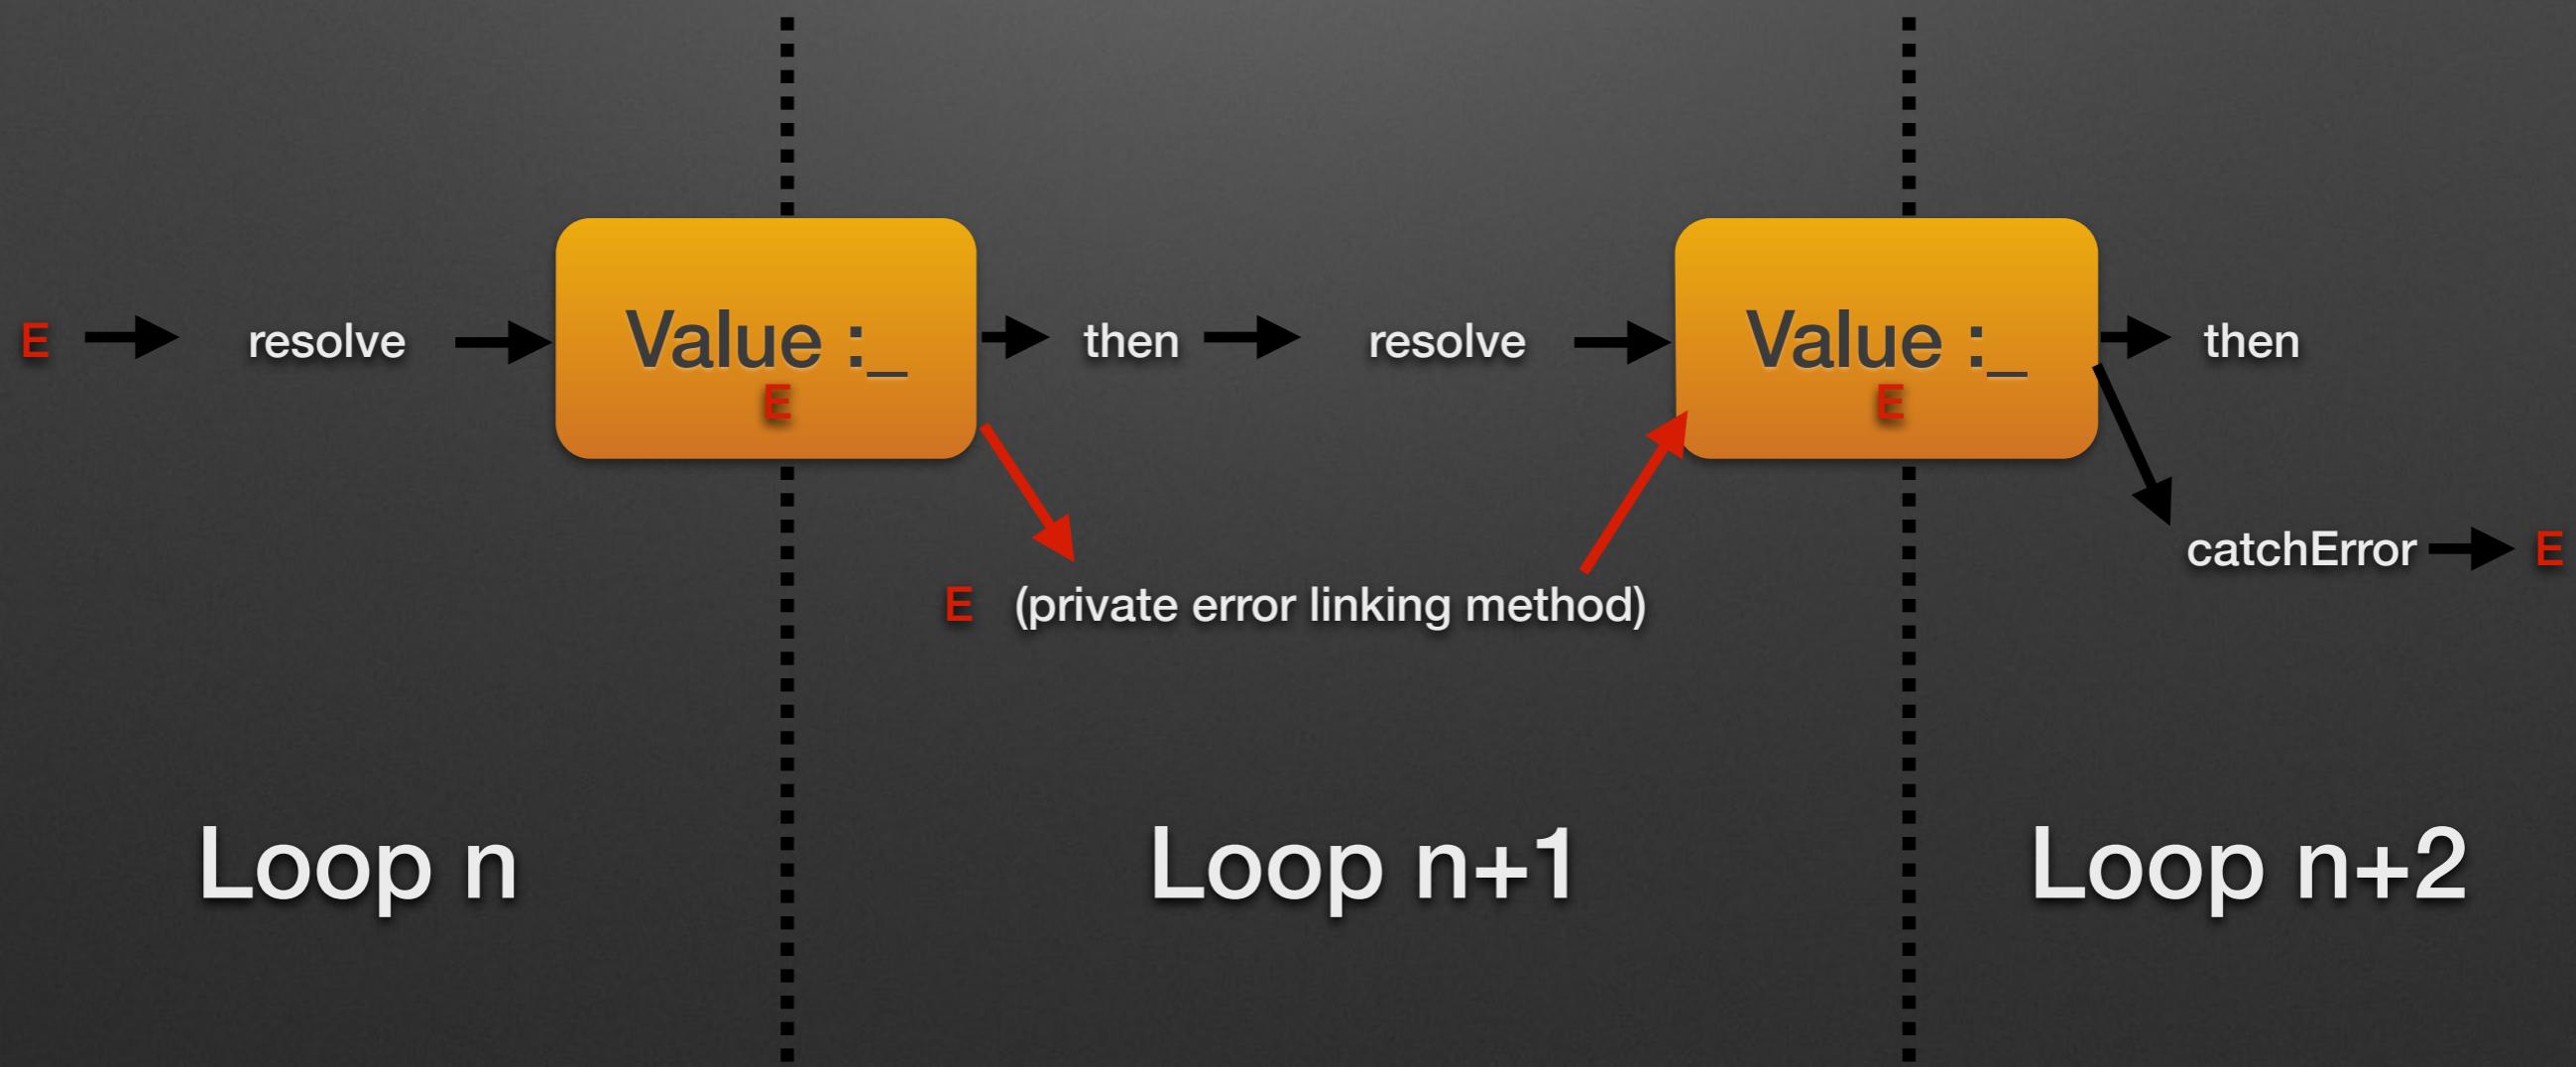

Promhx Object

Error Handling

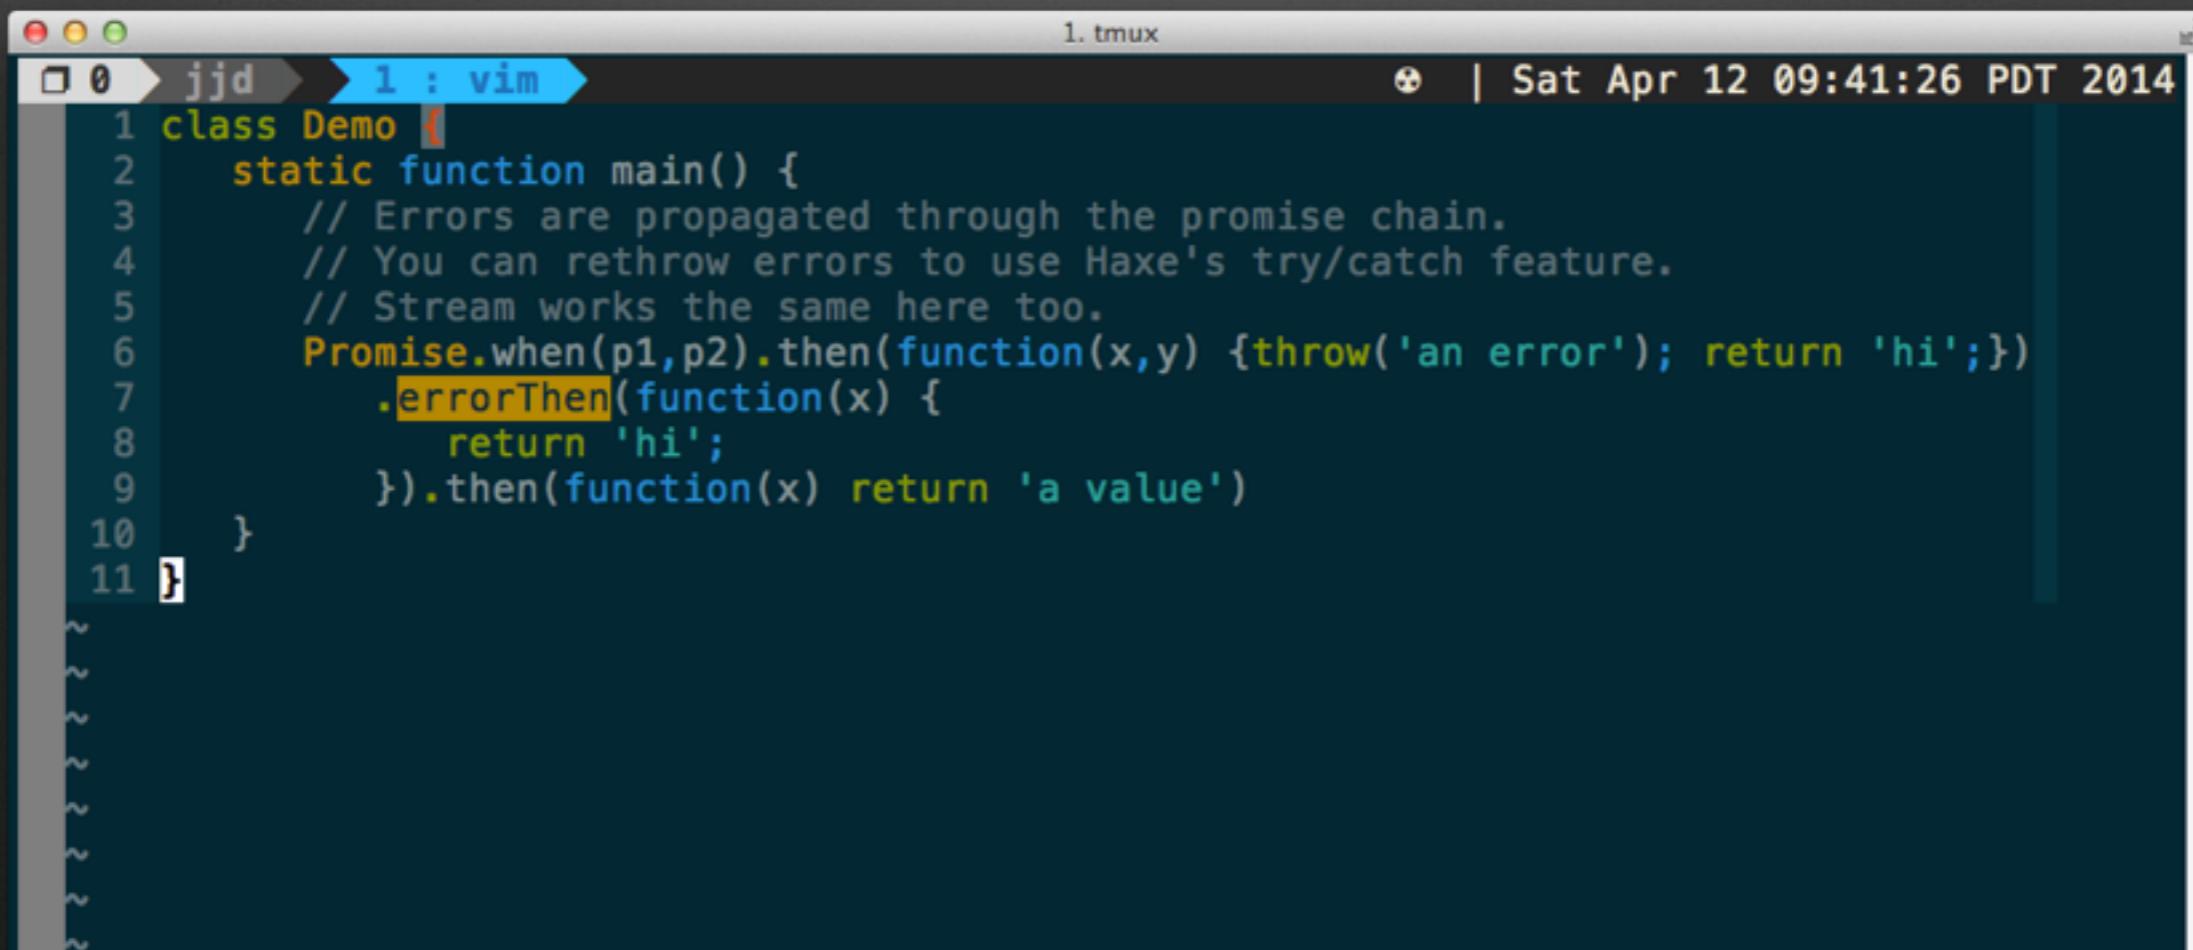

Promhx Object

Error Handling

Error handling

- `errorThen()` allows you to convert an error back into the appropriate variable type.
- This variable can be propagated as if it were resolved normally.

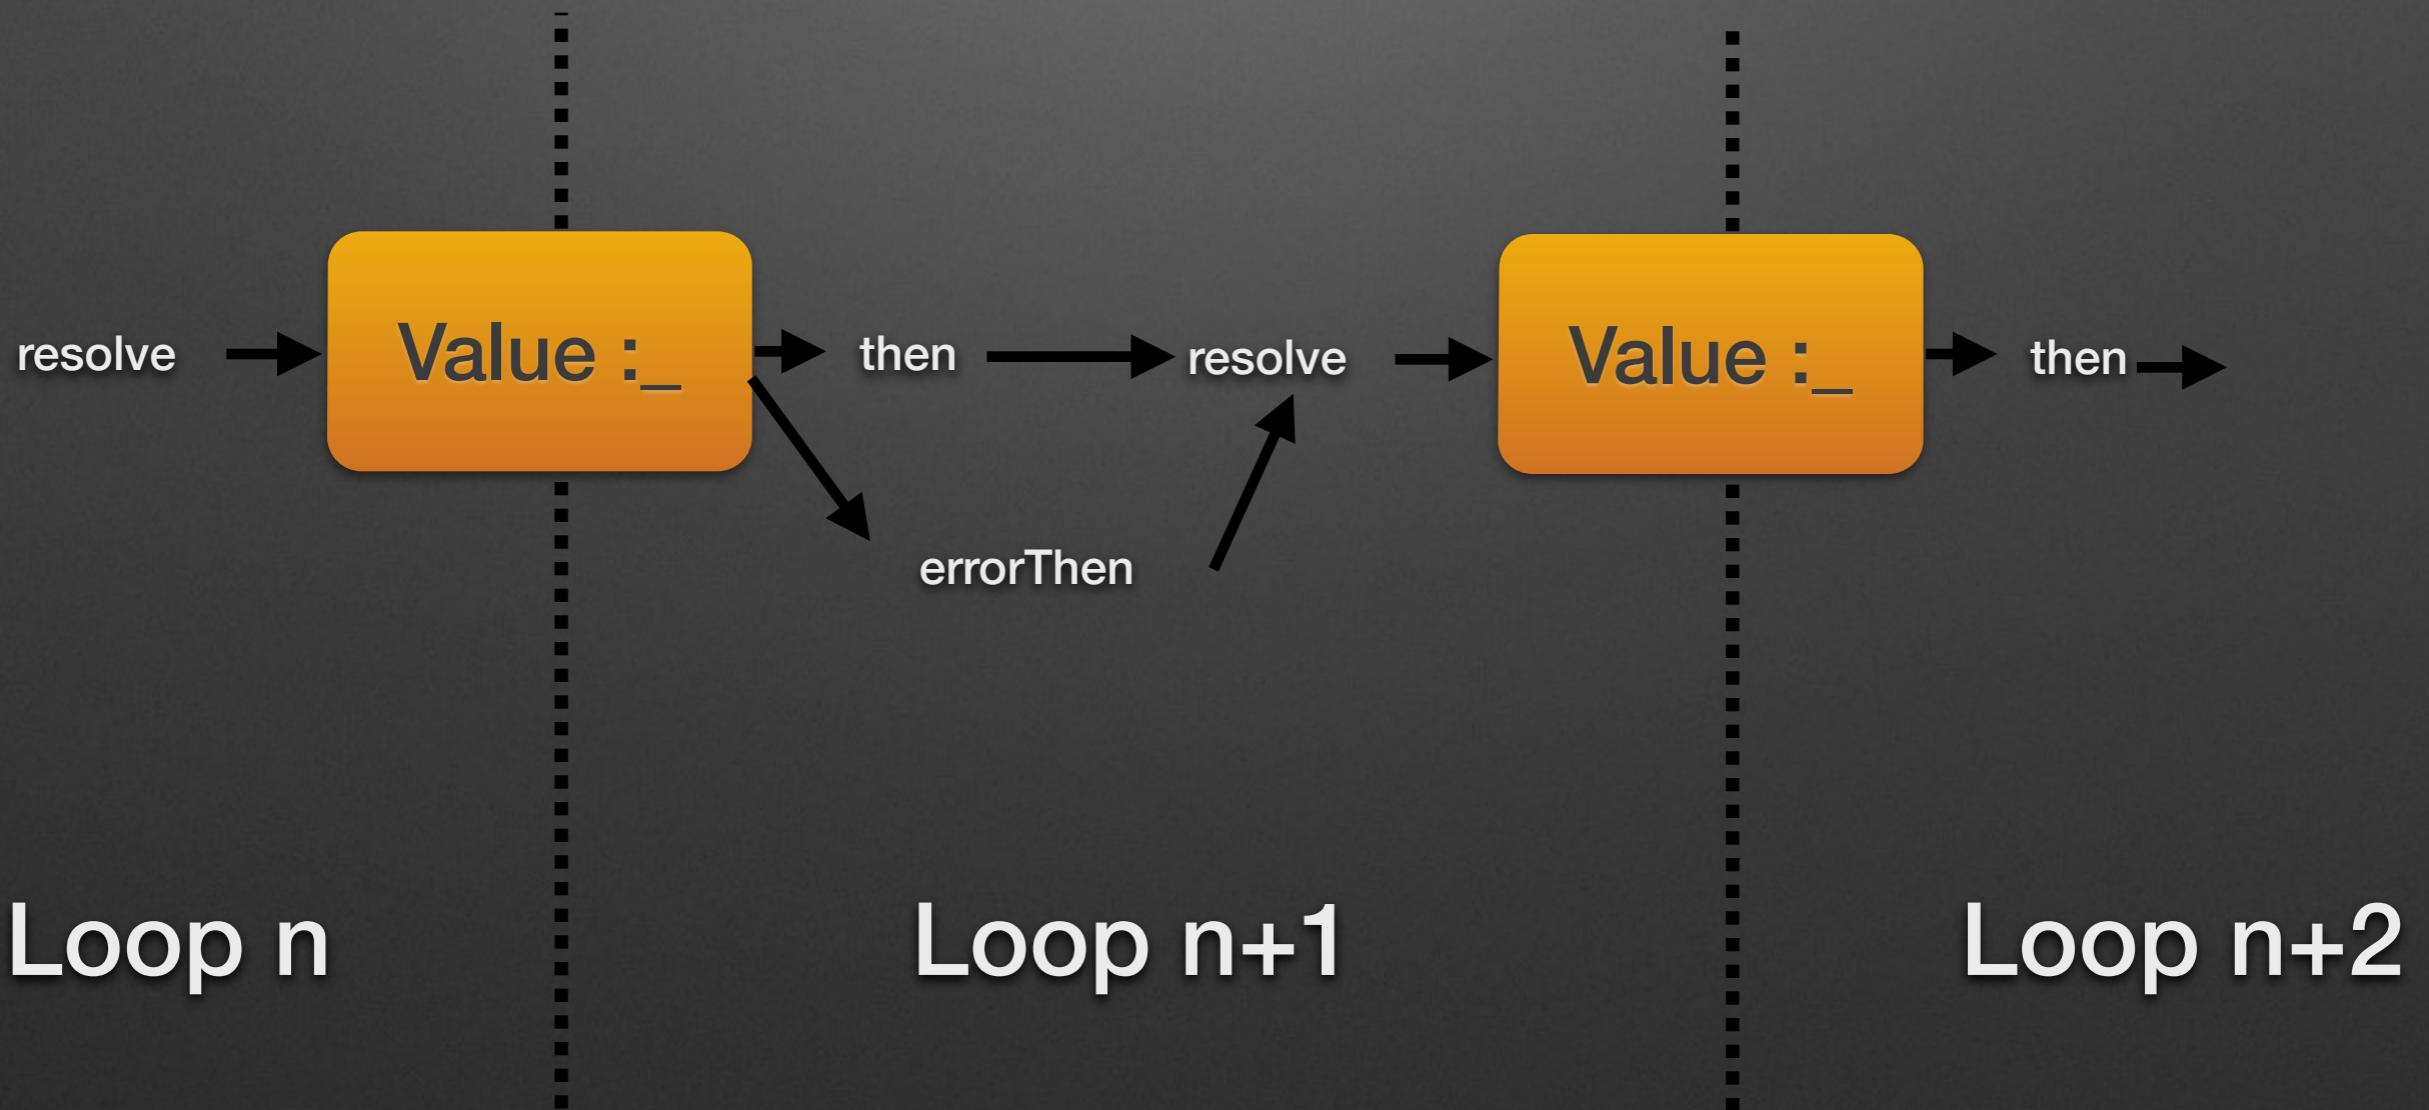

A screenshot of a tmux session titled "1. tmux". Inside the session, a vim window is open with the following Haxe code:

```
1 class Demo {
2     static function main() {
3         // Errors are propagated through the promise chain.
4         // You can rethrow errors to use Haxe's try/catch feature.
5         // Stream works the same here too.
6         Promise.when(p1,p2).then(function(x,y) {throw('an error'); return 'hi';})
7             .errorThen(function(x) {
8                 return 'hi';
9             }).then(function(x) return 'a value')
10    }
11 }
```

The code demonstrates a promise chain where an error is thrown and then handled by an `.errorThen()` block, which returns a value that is then processed by a final `.then()` block.

Are promhx objects Monads?

Three requirements for Monads:

- Type constructor : Create a monadic type for the underlying type. For example it defines type `Promise<Int>` for the underlying type `Int`. I.e. the class constructor
- unit function : Wraps a value of underlying type into a monad. For `Promise` monad it wraps value `2` of type `number` into value `Promise(2)` of type `Promise<Int>`. I.e. `Promise.promise`.
- bind function : Chains operations on monadic values. I.e. the “then” function.

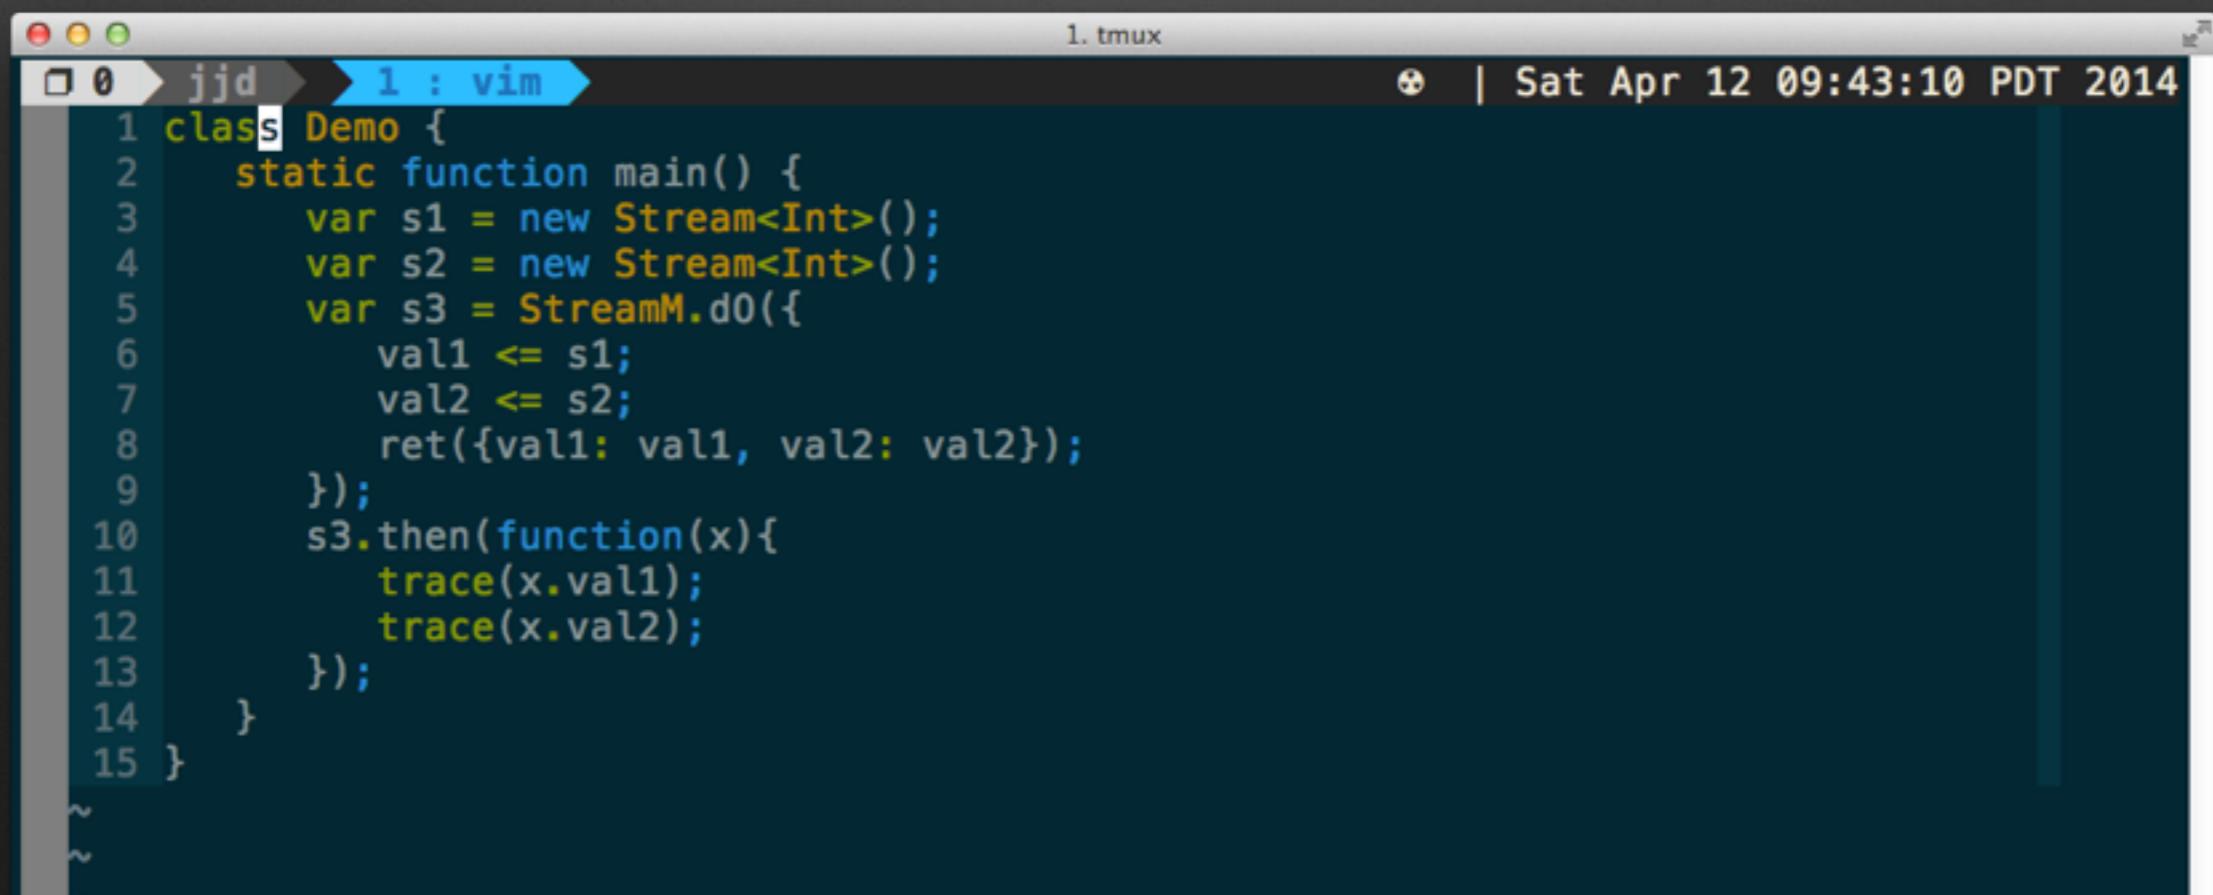

...So yes, but why should we care?

Monads are useful

- Allows for new capabilities for a given type, and allows the original functions to use the new capabilities.
- Captures operations on types, making it easier to build complex compositions that all behave by the same simple rules.
- Represents side-effecting operations cleanly in languages where this is problematic

Monad Composability

- Do-notation provided courtesy of Monax (Stephane Ledorze)
- The “<=“ operator binds the result returned via then()
- We can drop the chain syntax, and write out promises as if they were a simple series of expressions.

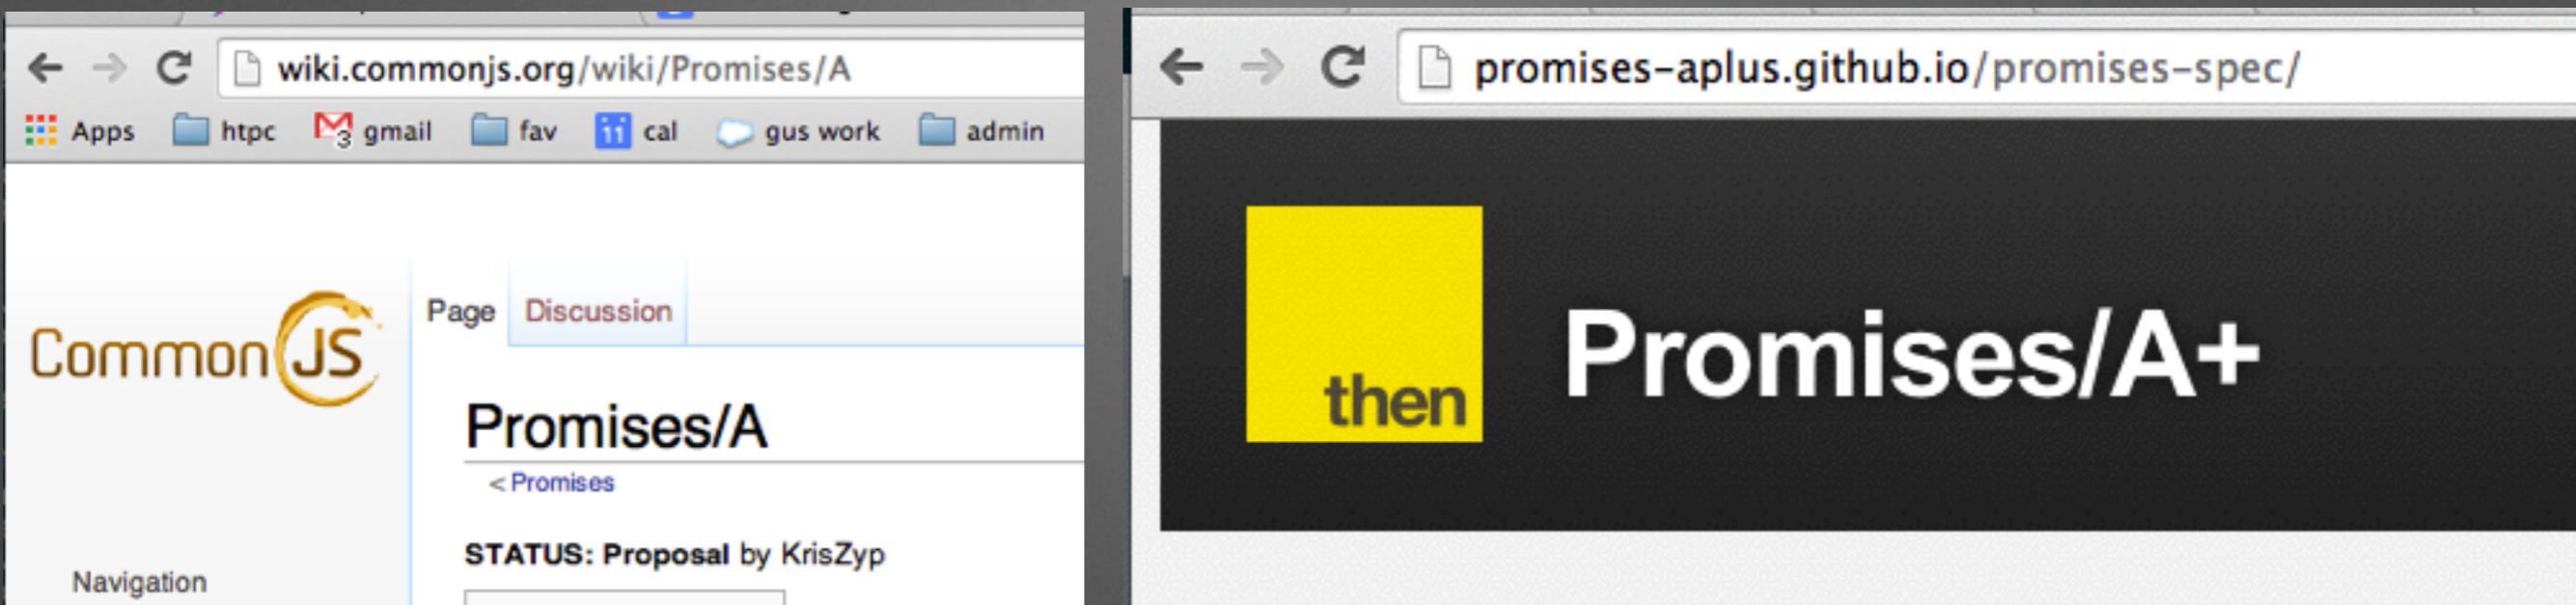

The screenshot shows a tmux session with one window titled "1 : vim". The code in the buffer is:

```
1 class Demo {
2     static function main() {
3         var s1 = new Stream<Int>();
4         var s2 = new Stream<Int>();
5         var s3 = StreamM.d0({
6             val1 <= s1;
7             val2 <= s2;
8             ret({val1: val1, val2: val2});
9         });
10        s3.then(function(x){
11            trace(x.val1);
12            trace(x.val2);
13        });
14    }
15 }
```

The code demonstrates the use of Stream and StreamM classes, and the d0 and then methods for creating and composing promises. The tmux status bar at the top right shows the date and time: "Sat Apr 12 09:43:10 PDT 2014".

Composability vs. Standards

- JS: callback usage is predominant, especially in platforms like node.
- Should we follow standards? Standards are good right?

Promises A+ Spec

Promise<Promise<T>?

2.3.1. If `promise` and `x` refer to the same object, reject `promise` with a `TypeError` as the reason.

2.3.2. If `x` is a promise, adopt its state [[3.4](#notes)]:

2.3.2.1. If `x` is pending, `promise` must remain pending until `x` is fulfilled or rejected.

2.3.2.2. If/when `x` is fulfilled, fulfill `promise` with the same value.

2.3.2.3. If/when `x` is rejected, reject `promise` with the same reason.

2.3.3. Otherwise, if `x` is an object or function,

2.3.3.1. Let `then` be `x.then`. [[3.5](#notes)]

2.3.3.2. If retrieving the property `x.then` results in a thrown exception `e`, reject `promise` with `e` as the reason.

2.3.3.3. If `then` is a function, call it with `x` as `this`, first argument `resolvePromise`, and second argument `rejectPromise`, where:

2.3.3.3.1. If/when `resolvePromise` is called with a value `y`, run [[Resolve]](`promise`, `y`) .

2.3.3.3.2. If/when `rejectPromise` is called with a reason `r`, reject `promise` with `r` .

2.3.3.3.3. If both `resolvePromise` and `rejectPromise` are called, or multiple calls to the same argument are made, the first call takes precedence, and any further calls are ignored.

2.3.3.3.4. If calling `then` throws an exception `e`,

2.3.3.3.4.1. If `resolvePromise` or `rejectPromise` have been called, ignore it.

2.3.3.3.4.2. Otherwise, reject `promise` with `e` as the reason.

2.3.3.4. If `then` is not a function, fulfill `promise` with `x` .

2.3.4. If `x` is not an object or function, fulfill `promise` with `x` .

Promhx Speed

That's it!

- I talked about why we need better asynchronous programming methods
- I talked about the basics of functional reactive programming
- I talked about the basic types of FRP that promhx supports, Promise, Stream, and PublicStream. I also talked about what each one is designed for, and how they use Deferred where appropriate.
- I talked about the way promhx handles errors and loop behavior
- I talked about some cool tricks that promhx can do since it behaves as a monad
- I talked about how fast and well tested the library is

QUESTIONS

We're Hiring!
